Table 10-719. RFBI_CONTROL

Address Offset	0x0000 0040		
Physical Address	0x5800 2040	**Instance**	RFBI
Description	The register configures the RFBI module.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							SMART_DMA_REQ	DISABLE_DMA_REQ	HIGHTHRESHOLD		ITE	CONFIGSELECT		RFBIMODE	ENABLE

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Write 0s for future compatibility. Reads return 0.	RO	0x000000
8	SMART_DMA_REQ	Smart DMA request 0x0: The dmareq is asserted and deasserted depending on FIFO space, even if MIdlereq is high in smart-idle/no-idle mode and the entire burst gets error responses from the module. 0x1: The dmareq is deasserted after 2 clock cycles, if it has been asserted for more than or equal to 2 clock cycles and MIdlereq is high in smart-idle or no-idle mode. No more burst requests are given, even if the space is available in the FIFO.	RW	0
7	DISABLE_DMA_REQ	Disable DMA request. 0x0: The dmareq is enabled and the signal is generated based on the space available and the request coming into the data register. 0x1: The dmareq is disabled and the signal is not generated at all based on space in FIFO. It stays high until the DISABLE DM AREQ is high even if there is space in FIFO to take requests.	RW	0
6:5	HIGHTHRESHOLD	Defines the FIFO high threshold used by hardware to assert DMA request. Used only if data written to RFBI_DATA are sent using sDMA. 0x0: Size of the transfer of 4 words of 32 bits wide 0x1: Size of the transfer of 8 words of 32 bits wide 0x2: Size of the transfer of 16 words of 32 bits wide	RW	0x0
4	ITE	Internal trigger 0x0: Hardware waits for the ITE bit to be set if in internal trigger mode for the configuration in use. 0x1: User sets the ITE bit to start the transfer. When hardware takes into account the bit, the hardware resets it.	RW	0

3D Accelerator GPU Subsystem

This chapter is a basic overview and describes the integration of the 3D graphics processing unit (GPU) subsystem in the device.

NOTE: The GPU subsystem is an instantiation by Texas Instruments of the POWERVR™ SGX544 core from Imagination Technologies Ltd.

This document contains materials that are © Imagination Technologies Ltd.

POWERVR and USSE are trademarks or registered trademarks of Imagination Technologies Ltd.

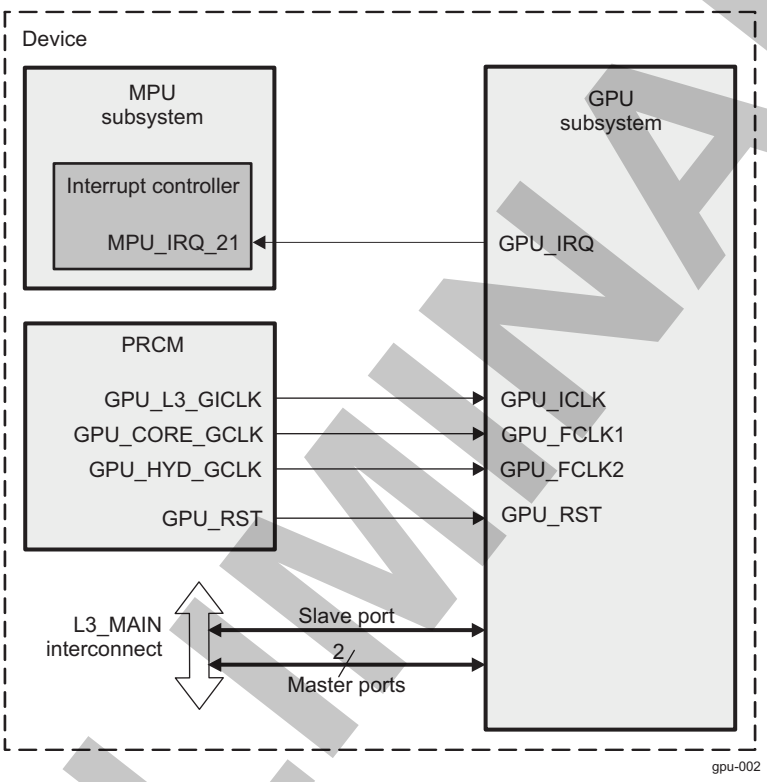
11.1 GPU Overview

The 3D graphics processing unit (GPU) accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics and compute applications. It is based on the POWERVR® SGX544-MP2 core from Imagination Technologies. The SGX544-MP2 core is a multicore evolution of the POWERVR SGX544 GPU.

The multicore GPU splits geometry and pixel rendering among the cores to improve performance proportional to the number of cores.

Figure 11-1 shows the GPU subsystem.

Figure 11-1. GPU Overview



11.1.1 GPU Features Overview

- API support for industry standards:
  - OGL-ES 1.1 and 2.0
  - OpenVG™ 1.1
  - OpenCL™-EP 1.1
  - Direct3D™ Feature Level 9.3
- Multicore GPU architecture:
  - 2 × SGX544 core
  - Shared system level cache of 128 KiB
- Tile-based deferred rendering architecture:
  - Reduces external bandwidth to SDRAM
- Universal Scalable Shader Engine (USSE™):
  - Multithreaded engine incorporating vertex and pixel shader functionality
  - Automatic load balancing of vertex and pixel processing tasks
- Present and texture load accelerator (PTLA):
  - Enables to move, rotate, twiddle, and scale texture surfaces

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

  - Supports RGB, ARGB, YUV4:2:2, and YUV4:2:0 surface formats
  - Supports bilinear upscale
  - Supports source color key
- Fully virtualized memory addressing for operating system (OS) in a unified memory architecture:
  - Memory management unit (MMU)
  - Up to 4-GiB virtual address space

11.1.2 Graphics Feature Overview

- Texture support:
  - Cube map
  - Projected textures
  - Non-square textures
- Texture formats:
  - RGBA 8888, 565, 1555, and 1565
  - Monochromatic 8, 16, 16f, 32f, and 32int
  - Dual channel, 8:8, 16:16, and 16f:16f
  - Compressed textures:
    - PVRTC-i 2 bpp
    - PVRTC-i 4 bpp
    - PVRTC-ii 2 bpp
    - PVRTC-ii 4 bpp
    - ETC1
    - DXT 1-5 and BC 4-5
  - Programmable support for YUV formats:
    - Programmable matrix in hardware, coefficients on 12 bits
    - YUV4:2;2, YUV4:2:0, two planes (NV12 or NV21); YUV4:2:0, three planes
- Resolution support:
  - Frame buffer maximum = 4096 × 4096
  - Texture maximum size = 4096 × 4096
- Texture filtering:
  - Bilinear, trilinear
  - Independent minimum and mag control
- Anti-aliasing:
  - 4× multisampling
  - Programmable sample positions

NOTE: TI provides the DXT1-5 and BC4-5 texture compression technology for use only with a Microsoft Windows operating system.

A separate license is required for the use of this technology (also referred to as S3 texture compression technology) with any other operating system.

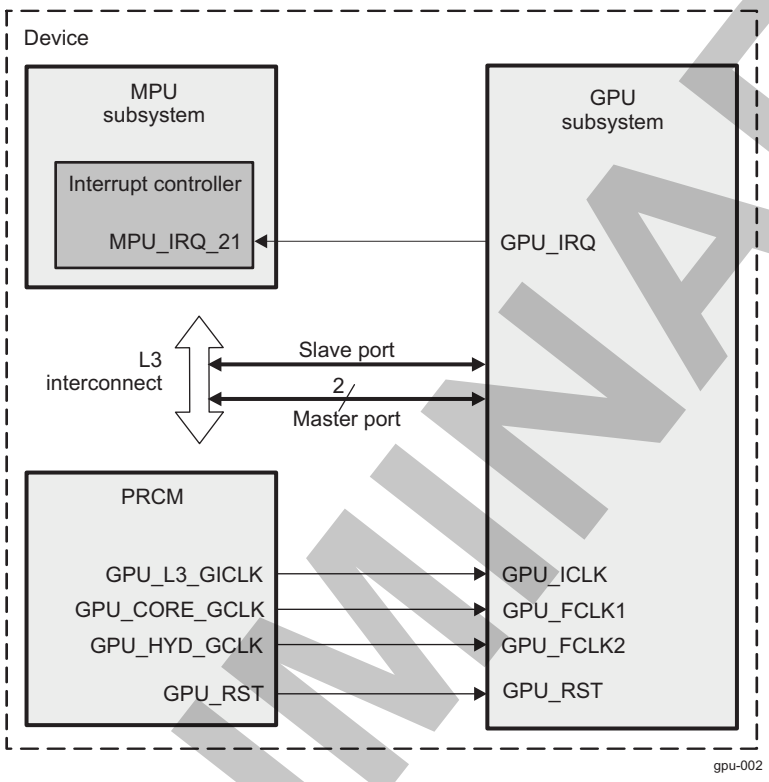
11.2 GPU Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 11-2 shows the GPU integration.

Figure 11-2. GPU Integration



The GPU subsystem is connected to the level 3 (L3) interconnect by two 128-bit master and a 64-bit slave interfaces.

Table 11-1 through Table 11-3 summarize the integration of the module in the device.

Table 11-1. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect

11.3 GPU Functional Description

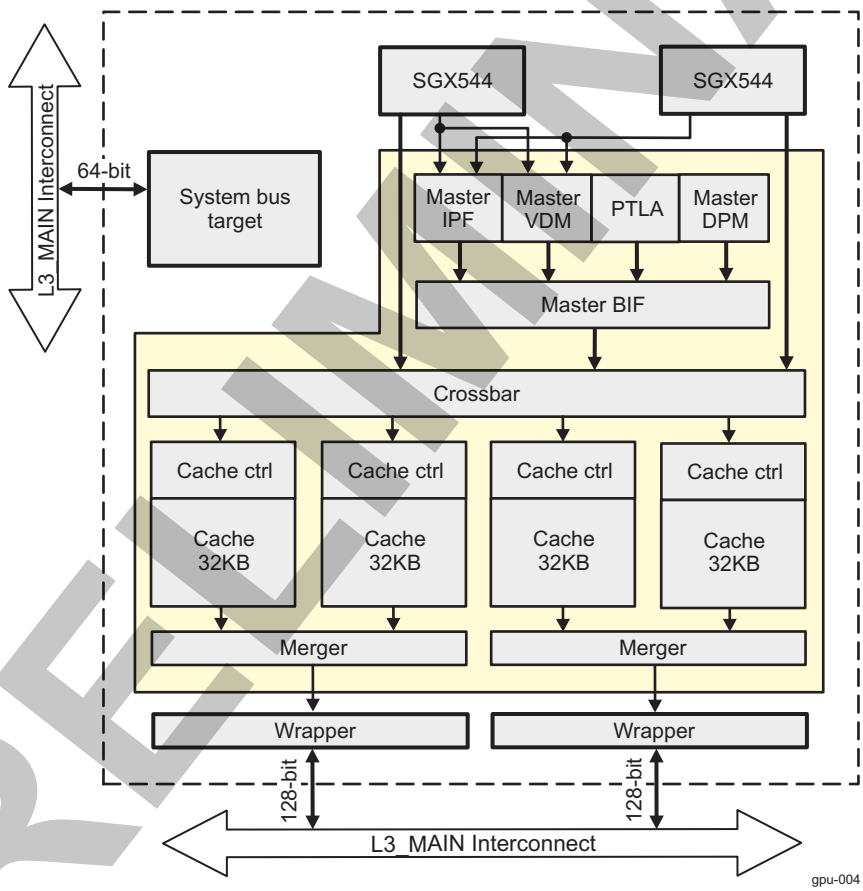
11.3.1 GPU Block Diagram

The GPU subsystem is based on the POWERVR SGX544-MP2 core. Multicore GPU can split geometry and pixel rendering among the cores to improve performance proportional to the number of cores. The graphics software engineer programming the OMAP5430 GPU does not have to deal with the multiple cores, this is done by the graphics drivers. The multiple cores are completely hidden behind the standard high-level graphics APIs that are supported by the graphics core. The GPU architecture comprises the following elements:

- SGX544 cores
- PTLA
- Cross bar
- System-level cache (SLC)

Figure 11-3 shows the GPU top-level block diagram.

Figure 11-3. GPU Block Diagram



The SGX544-MP2 has 2 × SGX544 cores. Graphics rendering is automatically load-balanced between the 2 × SGX544 cores. It is possible to disable one or two of the cores if required. The glue logic is used to enable the multicore architecture. The crossbar enables any SGX544 core to access the SLC. The SLC is a 128-KiB unified multibanked cache with four banks of 32 KiB. The cache line size is 64 bytes. The SGX544 core accesses are interleaved in the different banks.

11.3.2 GPU Clock Configuration

The GPU subsystem operates from three clocks: an interface clock (GPU_ICLK) and two functional clocks (GPU_FCLK1 and GPU_FCLK2). The power, reset, and clock management (PRCM) module generates and distributes the clocks inside the device.

- The GPU_ICLK manages the data transfer on the L3 master and slave ports.

  The GPU_ICLK frequency is selected based on the L3 interconnect clock frequency of the whole device. For more information about the interface clock, see Section 3.6.12, *CD_GPU Clock Domains*.

  When no longer required by the GPU subsystem, GPU_ICLK can be disabled by software at the PRCM level. For more information, see PD_GPU Description, in *Power, Reset, and Clock Management*.

  NOTE: GPU_ICLK is cut only if the GPU is ready to go into IDLE state.

- GPU_FCLK1 and GPU_FCLK2 are the functional clocks and are used inside the GPU subsystem to generate clock signals to multiple GPU clock domains.

  Using the clock source selection and the digital phase-locked loop (DPLL) settings, GPU_FCLK1 and GPU_FCLK2 frequencies can be adjusted.

  The GPU_FCLK1 and GPU_FCLK2 clocks are provided by the peripheral DPLL and the core DPLL, as described in CD_GPU Clock Domain, in *Power, Reset, and Clock Management*. Selection is made at the PRCM level.

  When no longer needed by the GPU subsystem, GPU_FCLK1 and GPU_FCLK2 can be cut by software at the PRCM level if the module is ready to enter IDLE state. For more information, see PD_GPU Description, in *Power, Reset, and Clock Management*.

11.3.3 GPU Software Reset

The GPU subsystem has its own reset domain. Global reset of the GPU is performed by activating the GPU_RST signal in the GPU_RST domain.

NOTE: The APIs delivered with the GPU provide a software reset functionally equivalent to a hardware reset.

11.3.4 GPU Power Management

The GPU subsystem has its own power domain (GPU power domain). For additional information about the GPU power domain, see PD_GPU Description, in *Power, Reset, and Clock Management*.

NOTE: The GPU handles automatic clock gating performed on the multiple internal module clock domains.

In addition, software-controlled clock gating is managed inside the GPU and handled by the related API delivered with the module.

11.3.5 GPU Interrupt Requests

The GPU subsystem can generate one interrupt signal to the MPU INTC mapped to GPU_IRQ.

11.4 GPU Register Manual

CAUTION

All GPU registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

2D Graphics Accelerator

This chapter describes the advanced bit blitter 2-dimensional (2D) graphics accelerator (BB2D) for the device.

NOTE: The BB2D subsystem is an instantiation by Texas Instruments of the GC320™ core from Vivante Corp.

This document contains materials that are © Vivante Corp.

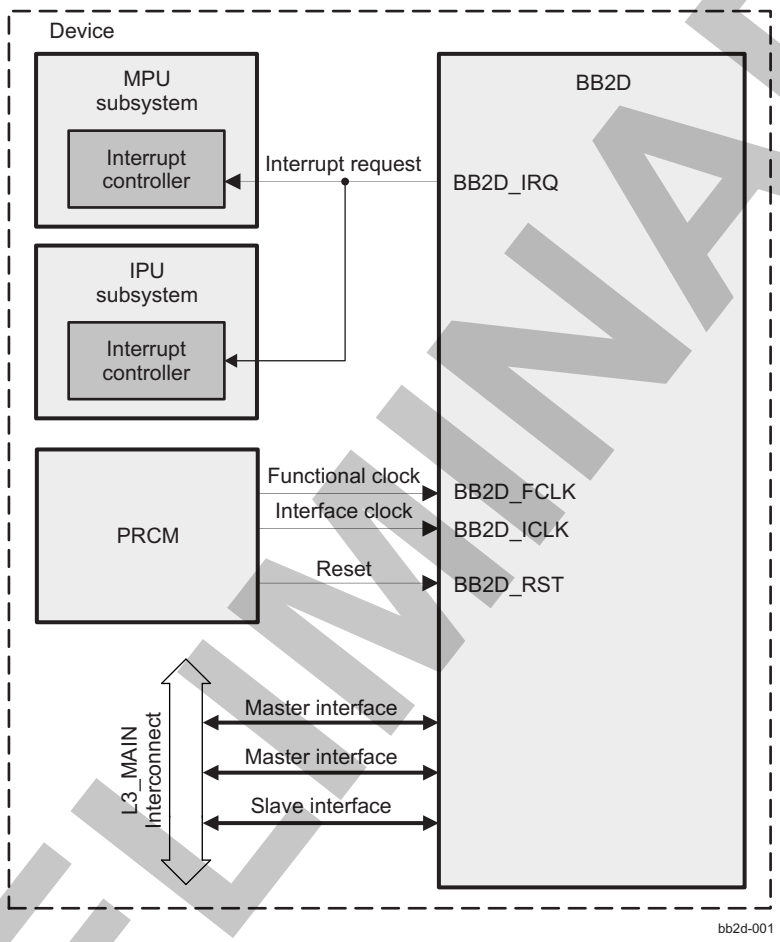
12.1 BB2D Overview

The 2D graphics accelerator subsystem accelerates 2D graphics applications. The 2D graphics accelerator subsystem is based on the GC320 2D GPU core from Vivante Corporation. The hardware acceleration is brought to numerous 2D applications, including on-screen display and touch screen user interfaces, graphical user interfaces (GUIs) and menu displays, flash animation, and gaming.

Figure 12-1 shows the BB2D subsystem.

Figure 12-1. BB2D Overview



12.1.1 BB2D Features Overview

- API support:
  - OpenWF™, DirectFB
  - GDI/DirectDraw™
  - Flash
- BB2D architecture:
  - BitBlt and StretchBlt
  - DirectFB hardware acceleration
  - ROP2, ROP3, ROP4 full alpha blending and transparency
  - Clipping rectangle support
  - Alpha blending includes Java® 2 Porter-Duff compositing rules
  - 90-, 180-, 270-degree rotation on every primitive
  - YUV-to-RGB color space conversion

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

  - Programmable display format conversion with 14 source and 7 destination formats
  - High-quality 9-tap, 32-phase filter for image and video scaling at 1080p
  - Monochrome expansion for text rendering
  - 32 K × 32 K coordinate system
- Hardware acceleration for DirectFB:
  - High-speed video scaler
  - ROP2/3/4
  - Rectangle filling and drawing
  - Line drawing
  - Simple blitting
  - Stretch blitting
  - Blending with alpha channel (per-pixel alpha)
  - Blending with alpha factor (alpha modulation)
  - Nine source and destination blending functions
  - Porter-Duff rules support
  - Premultiplied alpha support
  - Colorized blitting (color modulation)
  - Source color keying
  - Destination color keying

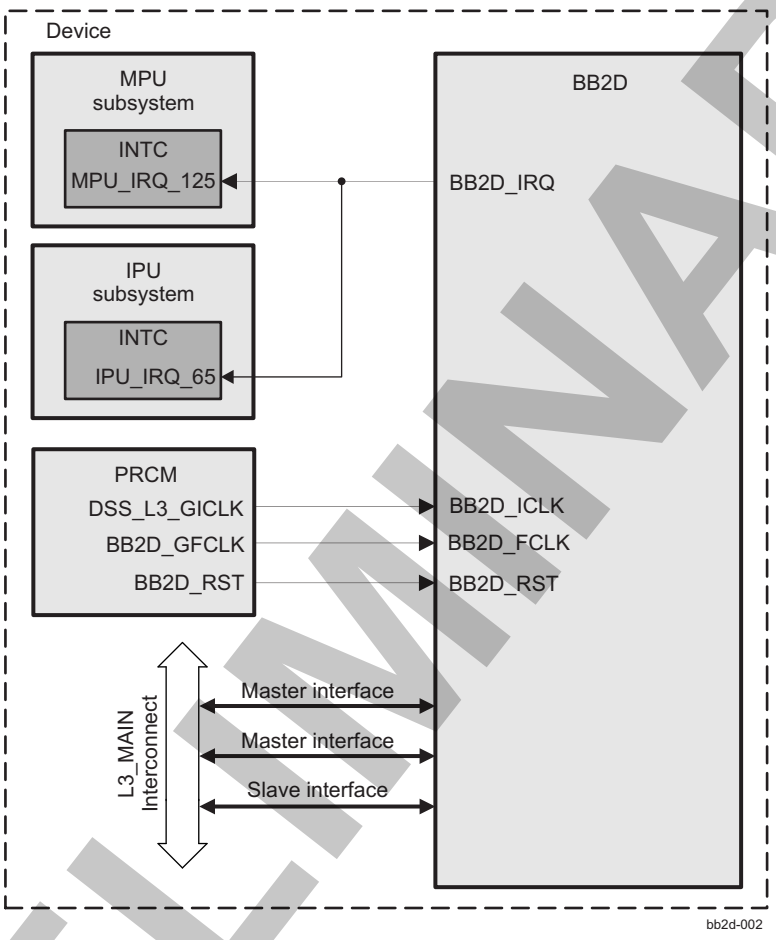
12.2 BB2D Integration

This section describes subsystem integration in the device, including information about clocks, resets, and hardware requests.

Figure 12-2 shows BB2D integration.

Figure 12-2. BB2D Integration



The BB2D subsystem is connected to the level 3 (L3_MAIN) interconnect by two 128-bit master interfaces and one 32-bit slave interface.

Table 12-1 through Table 12-3 summarize the integration of the subsystem in the device.

Table 12-1. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
BB2D	PD_DSS	L3_MAIN

Table 12-2. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
BB2D	BB2D_ICLK	DSS_L3_GICLK	PRCM	BB2D interfaces clock
	BB2D_FCLK	BB2D_GFCLK	PRCM	BB2D functional clock.
Resets

12.3 BB2D Functional Description

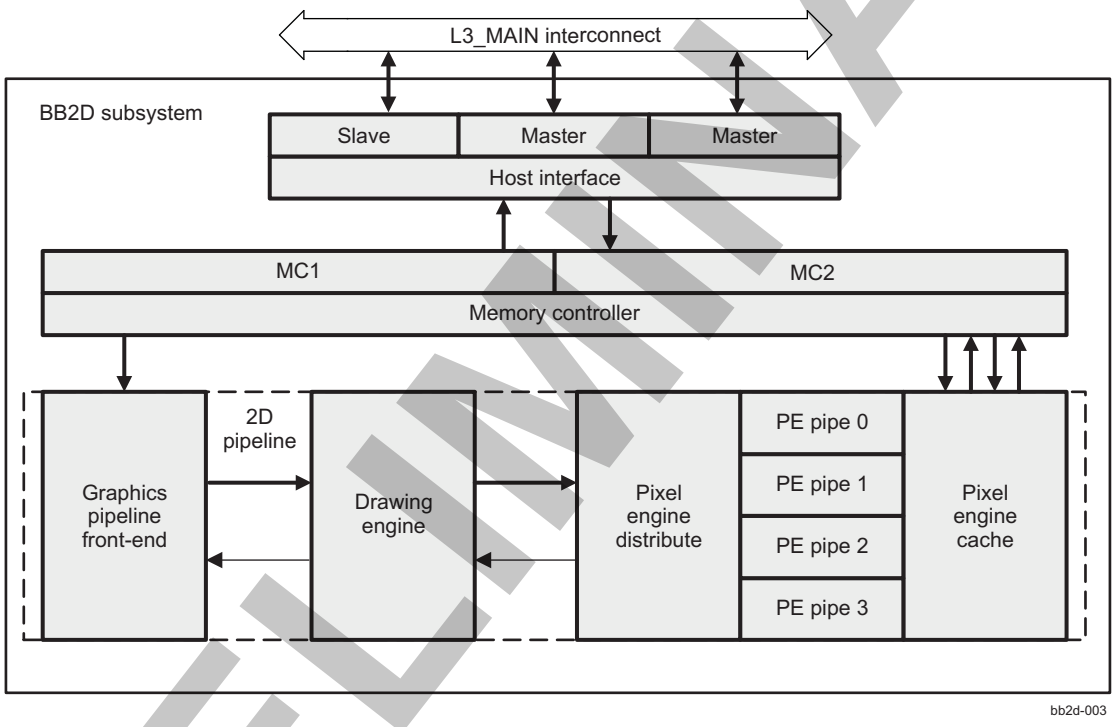
12.3.1 BB2D Block Diagram

The BB2D subsystem is based on the following main blocks:

- Host interface: Allows the BB2D core to communicate with external memory and the MPU through the L3_MAIN interconnect. In this block, data crosses clock domain boundaries.
- Memory controller: Internal memory unit that is the block-to-host interface for memory requests
- Graphics pipeline front-end: Inserts high-level primitives and commands into the graphics pipeline.
- 2D drawing and scaling engine: Draws 2D graphics primitives and rasterizes 2D images.
- Pixel engine: manipulates and filters pixels in rendered images. BB2D has four pixel pipes.

Figure 12-3 shows the BB2D top-level block diagram.

Figure 12-3. BB2D Block Diagram



12.3.2 BB2D Clock Configuration

The BB2D subsystem operates from two clocks: an interface clock (BB2D_ICLK) and functional clock (BB2D_FCLK). The power, reset, and clock management (PRCM) module generates and distributes the clocks inside the device.

- The BB2D_ICLK interface clock manages the data transfer on the L3_MAIN master and slave ports.

  The BB2D_ICLK frequency is selected based on the whole device L3 interconnect clock frequency. For more information on the interface clock, see *CD_DSS Clock Domain* in Section 3.6, *Clock Management Functional Description*.

  When BB2D_ICLK is no longer required by the BB2D subsystem, it can be disabled by software at the PRCM level.

  NOTE: BB2D_ICLK is cut only if the BB2D is ready to go into IDLE state.

- The BB2D_FCLK functional clock is used inside the BB2D subsystem to generate clock signals to multiple BB2D clock domains. The BB2D automatically gates clocks to domains, that are not currently in use.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Using the clock source selection and the DPLL settings, the frequency of BB2D_FCLK can be adjusted.

When BB2D_FCLK is no longer needed by the BB2D subsystem, it can be cut by software at the PRCM level, if the module is ready to enter IDLE state.

12.3.3 BB2D Software Reset

The BB2D subsystem is part of the DSS reset domain. A global reset of the BB2D is performed by activating the BB2D_RST signal in the DSS_RST domain.

NOTE: The APIs delivered with the BB2D provide a software reset functionally equivalent to a hardware reset.

12.3.4 BB2D Power Management

The BB2D subsystem is part of the DSS power domain (PD_DSS). For additional information about PD_DSS, see *PD_DSS Description* in Section 3.1.2.3, *Power Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.

NOTE: The BB2D handles automatic clock gating performed on the multiple internal clock domains.

When 2D operations are complete, software may set the GCGPOUT0[0] GCHOLD bit to 1 to enter a low-power state. Setting GCHOLD to 1 moves the BB2D operational state into IDLE. Once in IDLE state, the system standby hardware signal (mstandby) is asserted.

12.3.5 BB2D Interrupt Requests

The BB2D subsystem can generate one interrupt signal to the MPU INTC and to the IPU INTC mapped to BB2D_IRQ.

12.4 BB2D Register Manual

CAUTION

All BB2D registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

Bits	Field Name	Description	Type	Reset
31	FE20_BIT_INDEX	Supports 20 bit index.	R	1
30	RS_YUV_TARGET	Supports resolveing into YUV target.	R	1
29	BYTE_WRITE_3D	3D PE has byte write capability.	R	1
28	FE20	FE 2.0 is present.	R	0
27	VGTS	VG tesselator is present.	R	0
26	PIPE_VG	VG pipe is present.	R	0
25	MEM32_BIT_SUPPORT	32 bit memory address support.	R	0
24	YUY2_RENDER_TARGET	YUY2 support in PE and YUY2 to RGB conversion in resolve.	R	0
23	HALF_TX_CACHE	TX cache is half.	R	0
22	HALF_PE_CACHE	PE cache is half.	R	0
21	YUY2_AVERAGING	YUY2 averaging support in resolve.	R	1
20	NO_SCALER	No 2D scaler.	R	0
19	BYTE_WRITE_2D	Supports byte write in 2D.	R	1
18	BUFFER_INTERLEAVING	Supports interleaving depth and color buffers.	R	1
17	NO422_TEXTURE	No 422 texture input format.	R	0
16	NO_EZ	No early-Z.	R	0
15	MIN_AREA	Configured to have minimum area.	R	1
14	MODULE_CG	Second level clock gating is available.	R	1
13	YUV420_TILER	YUV 4:2:0 tiler is available.	R	1
12	HIGH_DYNAMIC_RANGE	Shows if there is HDR support.	R	1
11	FAST_SCALER	Shows if there is HD scaler.	R	1
10	ETC1_TEXTURE_COMPRESSION	ETC1 texture compression.	R	1
9	PIPE_2D	Shows if there is 2D engine.	R	1
8	DC	Shows if there is a display controller.	R	0
7	MSAA	MSAA support.	R	1
6	YUV420_FILTER	YUV 4:2:0 support in filter blit.	R	1
5	ZCOMPRESSION	Depth and color compression.	R	0

Bits	Field Name	Description	Type	Reset
31	ENHANCE_VR	Enhance VR and add a mode to walk 16 pixels in 16-bit mode in vertical pass to improve cache hit rate when rotating 90/270.	R	1
30	CORRECT_STENCIL	Correct stencil behavior in depth only.	R	1
29	A8_TARGET_SUPPORT	2D engine supports A8 target.	R	0
28	NEW_TEXTURE	New texture unit is available.	R	0
27	HIERARCHICAL_Z	Hierarchiccal Z is supported.	R	1
26	BYPASS_IN_MSAA	Shader supports bypass mode when MSAA is enabled.	R	0
25	VAA	VAA is available or not.	R	0
24	BUG_FIXES0		R	1
23	SHADER_MSAA_SIDEBAND	Put the MSAA data into sideband fifo.	R	0
22	MC_20	New style MC with separate paths for color and depth.	R	0
21	DEFAULT_REG0	Unavailable registers will return 0.	R	1
20	EXTRA_SHADER_INSTRUCTIONS1	Sqrt, sin, cos instructions are available.	R	1
19	SHADER_GETS_W	W is sent to SH from RA.	R	1
18	VG_21	Minor updates to VG pipe (Event generation from VG, TS, PE). Tiled image support.	R	0
17	VG_FILTER	VG filter is available.	R	0
16	EXTRA_SHADER_INSTRUCTIONS0	Floor, ceil, and sign instructions are available.	R	1

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
15	COMPRESSION_FIFO_FIXED	If this bit is not set, the FIFO counter should be set to 50. Else, the default should remain.	R	1
14	TS_EXTENDED_COMMANDS	New commands added to the tessellator.	R	0
13	VG_20	Major updates to VG pipe (TS buffer tiling. State masking.).	R	0
12	SUPER_TILED_32X32	32 × 32 super tile is available.	R	1
11	SEPARATE_TILE_STATUS_WHEN_INTERLEAVED	Use 2 separate tile status buffers in interleaved mode.	R	1
10	TILE_STATUS_2BITS	2 bits are used instead of 4 bits for tile status.	R	1
9	RENDER_8K	Supports 8K render target.	R	1
8	CORRECT_AUTO_DISABLE	Reserved.	R	0
7	PE20_2D	2D PE 2.0 is present.	R	1
6	FAST_CLEAR_FLUSH	Proper flush is done in fast clear cache.	R	1
5	SPECIAL_MSAA_LOD	Special LOD calculation when MSAA is on.	R	1
4	CORRECT_TEXTURE_CONVERTER	Driver hack is not needed.	R	1
3	TEXTURE8_K	Supports 8K × 8K textures.	R	1
2	ENDIANNESS_CONFIG	Configurable endianness support.	R	1
1	DUAL_RETURN_BUS	Dual Return Bus from HI to clients.	R	1
0	FLIP_Y	Y flipping capability is added to resolve.	R	1

Table 12-90. GCDISPLAYPRIORITY

Address Offset	0x0000 0434		
Physical Address	0x5900 0434	**Instance**	BB2D
Description	Controls the priority of the display controller requests. This works like a PWM. One register gives the period, and the other gives the ON time. When PWM is ON, display requests are accepted if both display and the other request is valid. If it is OFF, the other request will be accepted. If only one request is valid, it takes the bus regardless of the PWM bit.

Audio Back End

This chapter describes the audio back end (ABE) module.

Topic **Page**

13.1 ABE Overview **3118**

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

13.1 ABE Overview

The audio back end (ABE) module is a subsystem that manages various audio and voice uplink and downlink streams between the initiator (the Cortex™-A15 microprocessor unit [MPU], digital signal processor [DSP], or direct memory access [DMA] controller) and the peripheral physical interfaces (multichannel buffered serial port [MCBSP], digital microcontroller [DMIC], multichannel pulse density modulation [MCPDM], and multichannel audio serial port [MCASP]).

The ABE module handles the audio processing for the applications. It receives voice or audio samples from the initiator or the external audio chip (TWL6041 or other) and sends them to the peripheral interfaces or memories after processing. The ABE can perform buffering of audio samples, mix audio with a voice downstream and/or a microphone upstream (sidetone), and can apply some post-processing.

The ABE integrates the following modules:

- Peripheral physical interfaces:
  - Three MCBSP modules
  - One MCASP module
  - One DMIC module to support up to six mono and three stereo digital microphones
  - One MCPDM module to support interconnect with an external audio chip
- Audio engine (AE):
  - Performs real-time signal processing, such as sample rate conversion, filtering, equalizing, and side-tone
  - Audio traffic controller (ATC):
    - Performs data move in the ABE
    - Generates interrupt requests to the DSP and Cortex-A15 interrupt controllers (INTCs)
  - On-chip memory:
    - 64KiB of RAM; 32-bit data memory (DMEM)
    - 6KiB for coefficient memory RAM (CMEM)
    - 18KiB for sample memory RAM (SMEM)
- Local level 4 (L4) interconnect (L4_ABE) to:
  - Level 3 (L3) interconnect
  - Cortex-A15 MPU
  - DSP

  The Cortex-A15 MPU and the DSP have private access to the L4_ABE interconnect. All other initiators (DMA_SYSTEM) can access the L4_ABE interconnect only through the L3 interconnect.
- Timers:
  - Four general-purpose (GP) timers
  - One watchdog timer
- Clock and reset management: Receives clock and reset signals from the device power, reset, and clock management (PRCM) module. The audio engine operates from the DPLL_ABE, which is in the PRCM module. Clock signals from the DPLL_ABE or the DPLL_PER can supply the ABE modules. The ABE has its own hardware reset domain (AUDIO_RST).
- Power management: The ABE module is power-independent. It has its own dedicated power domain (PD_ABE) and can execute audio processing with the rest of the device in retention or off mode.
- The initiator can directly access each peripheral in the ABE when the AE is bypassed (legacy mode, for old software compatability).

Figure 13-1 is a high-level overview of the ABE.

PRELIMINARY

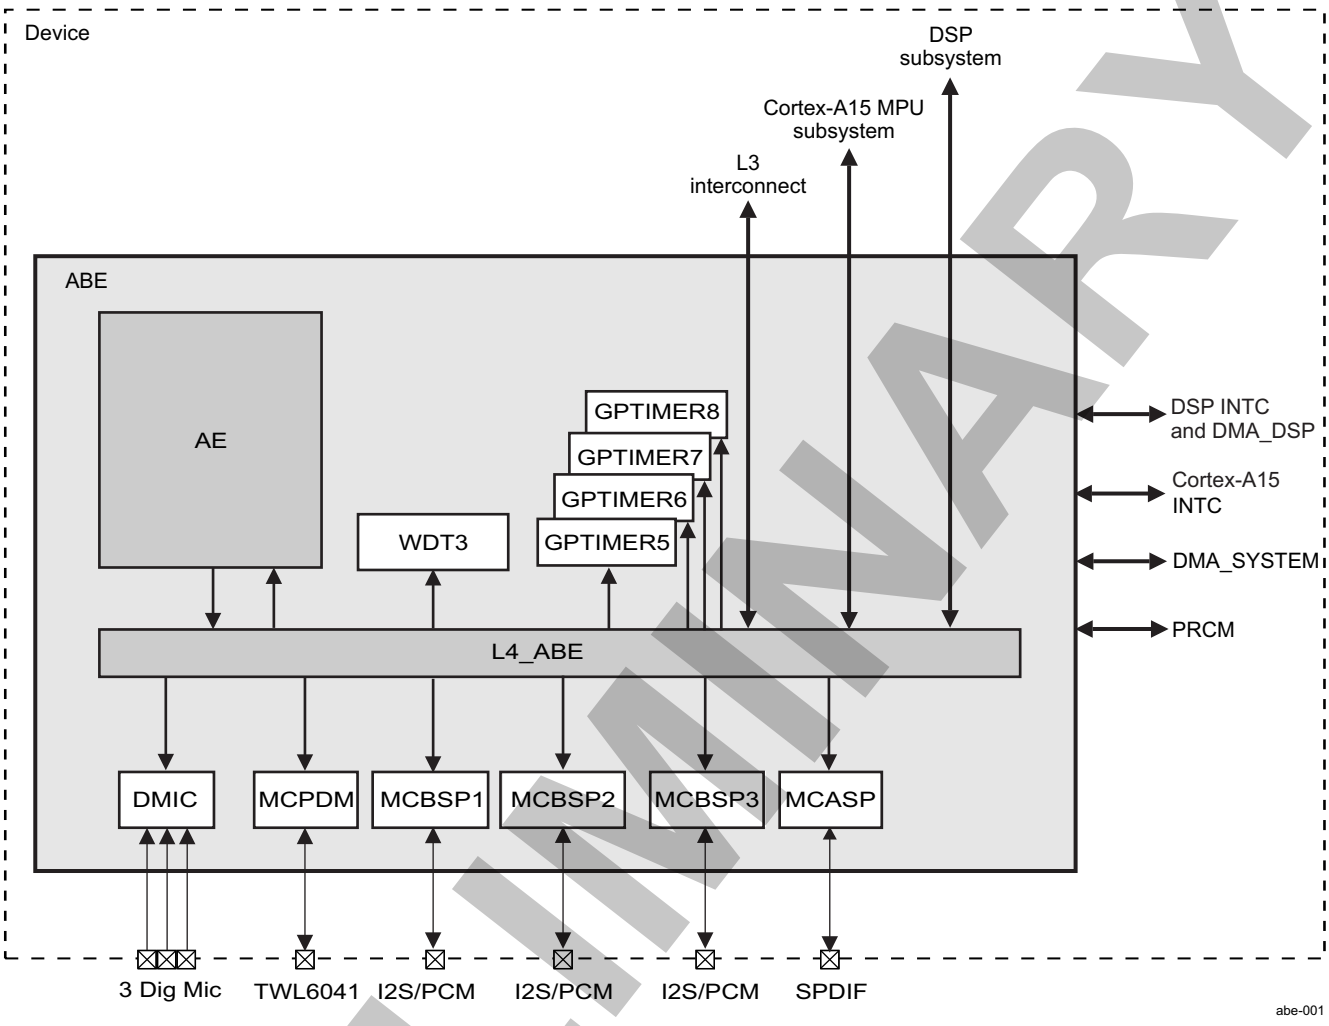
Figure 13-1. Audio Back End



13.1.1 AE Subsystem

The AE is the core of the ABE subsystem. It performs the real-time audio processing within the ABE:

- Mixing
- Muxing
- Volume control
- Smooth muting
- Sampling rate conversion
- Side-tone equalization

The AE subsystem also processes and executes all data transfers. To optimize the global processing, the ATC moves the data. An interrupt request (IRQ)/DMA controller controls system IRQs and DMA requests. Input DMA requests come from the ABE peripherals, and output DMA requests and IRQs are generated and sent to the system (Cortex-A15 MPU INTC, DSP INTC, system DMA [DMA_SYSTEM], and the DSP enhanced DMA controller [DMA_DSP]).

The AE subsystem contains:

- AE: Processes the sample in SMEM with the help of CMEM:
  - SMEM
  - CMEM

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- DMEM: Contains the audio buffer and communication circular buffer
- ATC: Transfers data between all modules in the ABE
- IRQ DMA controller

For more information about the audio engine, see the *Hardware Abstraction Layer (HAL) Addendum*.

13.1.2 Local Audio Interconnect

The ABE has its own audio local interconnect (L4_ABE), which interconnects and manages the data flow among all ABE modules.

The main features of the L4_ABE are:

- Initiator ports:
  - Cortex-A15 MPU
  - DSP
  - L3 interconnect
  - AE subsystem

  The sDMA operates with the L4_ABE interconnect through the L3 interconnect initiator port. The DMA_DSP operates with the L4_ABE interconnect through the DSP initiator port.
- Target ports:
  - AE subsystem
  - MCBSP1, MCBSP2, and MCBSP3
  - DMIC
  - MCPDM
  - MCASP
  - GPTIMER5 through GPTIMER8
  - WDT3
- 8-, 16-, or 32-bit data, single access
- 4-bit × 32-bit initiator ports for each interconnect instance
- Auto clock-gating feature
- Little-endian transaction assumed for all packing or unpacking operations
- Nonblocking architecture with fair arbitration between threads
- Target interconnect interfaces support fully synchronous and divided synchronous accesses.

For more information, see Chapter 14, *Interconnect*.

13.1.3 GP Timers

The ABE embeds four GP timers: GPTIMER5 through GPTIMER8. All GP timers have interrupts connected to the Cortex-A15 MPU, DSP, and AE subsystems.

GP timer controllers have the following functions:

- Interconnect slave interface (L4) supports:
  - 32-bit data bus width
  - 16- and 32-bit access
  - 10-bit address bus width
  - Write-Non-Posted (WNP)

  Burst is not supported.
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Supported modes:

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

  - Compare and capture modes
  - Auto-reload mode
  - Start-stop mode
- Programmable divider clock source
- Dedicated input trigger for capture mode and dedicated OUT trigger/pulse width modulation (PWM) signal
- On-the-fly read/write register
- The disconnect protocol

For more information, see Section 22.2, *General-Purpose Timers*.

13.1.4 Watchdog Timer

The ABE embeds one watchdog timer, WDT3, that generates an interrupt condition to the Cortex-A15 MPU on overflow. Application software can use an overflow to indirectly trigger a global warm reset through the PRCM module.

The main features of the WDT3 are:

- Interconnect slave interface (L4) supports:
  - 32-bit data bus width
  - 16- and 32-bit access
  - 11-bit address bus width
  - WNP

  Burst is not supported.
- Free-running 32-bit upward counter
- Programmable divider clock source
- Watchdog is reset on power up or after a warm reset and then starts counting.
- Reset or interrupt actions on a timer overflow condition and according to the watchdog timer source
- The disconnect protocol

For more information, see Section 22.3, *Watchdog Timers*.

13.1.5 Digital Microphone Controller

The DMIC allows support of up to three digital stereo microphones, which send it a pulse-density modulated stream of bits that are transferred on one period or one half-period of the clock (over-sampling clock) provided to the DMIC. Each microphone is connected directly to the TX filter decimator to extract the audio samples with a maximum of 96 db SNR with a frequency sampling set to 96 kHz.

The DMIC has the following features:

- Has six external pin connections (three data lines and three clock lines)
- Delivers one common clock (on the three clock lines) for all digital microphones
- Supports idle request and idle acknowledge protocol
- Supports stereo and mono digital microphones (up to three)
- Supoorts rising or falling edge configuration for the clock signal sampling
- Is DMIC-clock-programmable
- Has an interconnect slave interface (internal interconnect) that supports 32-bit data bus width.
- Has one DMA request capability on a programmable first in first out (FIFO) threshold
- Supports one RX FIFO (16-bit × 24-bit word depth) per microphone
- Complies with PRCM interrupts to the Cortex-A15 MPU and DSP subsystems
- Supports interconnect sample format: 32 bits (only 24 are significant)
- Supports idle request and idle acknowledge PRCM protocol

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

For more information, see Section 23.7, *Digital Microphone Module*.

13.1.6 Multichannel Audio Serial Port

The MCASP is a GP audio serial port. It is useful for intercomponent (DIT) transmission. The MCASP is intended to be flexible enough so that it can connect gluelessly to audio A/D, D/A, CODEC, SPDIF transmit and recieve physical layer components and clocked frame-oriented protocols (inter-IC sound [I2S] and time division multiplexing [TDM]).

The MCASP has the following features:

- 2-interconnect slave interface supports:
  - One interconnect configuration slave interface
  - One interconnect DMA slave interface
  - 32-bit data bus width
  - 16- and 32-bit access
  - 10-bit address bus width
  - WNP

  Burst is not supported.
- Supports idle request/acknowledge protocol
- Buffers for transmit/receive operations
- DMA requests (one per direction) link with the 32-bit register
- Up to four transmit and receive channels
- Four serializers implemented
- Support of disconnect protocol

For more information, see Section 23.8, *MCASP*.

13.1.7 Multichannel Buffered Serial Port

There are three MCBSP instantiations: MCBSP1 through MCBSP3. They provide a full-duplex direct serial interface between the ABE and external devices, such as Bluetooth chips, or codecs. Because of its versatility, a MCBSP can accommodate a wide range of peripherals and clocked frame-oriented protocols (I2S, PCM, and TDM).

The recommended use per MCBSP is:

- MCBSP1: Bluetooth voice/audio data
- MCBSP2: Digital baseband (DBB) voice data
- MCBSP3: MIDI FM data

The MCBSP has the following features:

- Interconnect slave interface (internal interconnect) supports:
  - 32-bit data bus width
  - 8-, 16-, and 32- bit access
  - 10-bit address bus width
  - WNP

  Burst is not supported.
- Buffers for transmit/receive operations: 128/128 32-bit words (MCBSP1, 2, 3)
- Interrupts configurable in legacy mode (two requests) or PRCM module-compliant (one request)
- DMA requests (one per direction) triggered with programmable FIFO thresholds
- Multidrop support
- Serial interface description
- Four-pin configuration (MCBSP1, 2, 3)

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- Full-duplex communication
- Multichannel selection modes
- Support to enable or block transfers in each channel
- Up to 128 channels for transmission and for reception
- Supported protocols
- Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices:
  - I2S-compliant devices
  - TDM bus devices
  - PCM devices
- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
- Supports idle request/acknowledge protocol
- Clock generation support:
  - Independent clocking and framing for reception and transmission up to 48 MHz
  - Support for external generation of clock signals and frame-synchronization (frame-sync) signals
  - A programmable sample rate generator for internal generation and control of clock signals and frame-sync signals
- Support of disconnect protocol

For a complete description, see Section 23.5, *Multichannel Buffered Serial Port (MCBSP)*.

13.1.8 Multichannel Pulse Density Modulation Module

The MCPDM is a proprietary interface based on multichannel pulse density modulation. The module consists of five downlinks and three uplinks. Two other uplink channels are reserved for status communication.

The MCPDM has the following features:

- Interconnect slave interface (L4_ABE internal interconnect) supports:
  - 32-bit data bus width
  - 10-bit address bus width
  - WNP

  Burst is not supported.
- Full-duplex communication:
  - Five audio downstream channels
  - Three audio upstream channels
- RX/TX FIFO operations: 32-bit words per channel
- Complies with PRCM module interrupts:
  - One to the MPU subsystem
  - One to the DSP subsystem
- DMA requests (one per direction) triggered with programmable FIFO thresholds; depending on the FIFO implementation, one request per channel or one per direction
- Decimation filter for embedded uplink paths (five paths if two status paths)
- Oversampling for embedded uplinks (five paths)
- Sigma-delta for embedded downlinks (three paths)
- Deserializers for the two status upstream channels
- Support of disconnect protocol

For more information, see Section 23.6, *Multichannel PDM Controller*.

14.1 Interconnect Overview

14.1.1 Terminology

The following terminology is critical to understanding the interconnect:

- Initiator: Module able to initiate read and write requests to the chip interconnect (typically: processors, direct memory access (DMA), and so forth).
- Target: Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals and memory controllers).

NOTE: A module can have several separate ports; therefore, a module can be an initiator and a target.

- Agent: Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).
- Interconnect: The decoding, routing, and arbitration logic that enables the connection between multiple initiator modules and multiple target modules connected on it
- Register target (RT): Special TA used to access the interconnect internal configuration registers
- Data-flow signal: Any signal that is part of a clearly identified transfer or data flow (typically: command, address, byte enables, and so forth). Signal behavior is defined by the protocol semantics.
- Sideband signal: Any signal whose behavior is not associated to a precise transaction or data flow
- Out-of-band error: Any signal whose behavior is associated to a device error-reporting scheme, as opposed to in-band errors

NOTE: Interrupt requests and DMA requests are not routed by the interconnect in the device.

- Firewall: A programmable feature integrated in a TA or level 4 (L4) interconnect to prevent unauthorized access to or from a module. A firewall can be configured using three criteria:
  - Initiator requesting access
  - Address space access
  - Type of access
- ConnID: Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted in band with the request and is used for firewall and error-logging mechanism.
- Firewall comparison mechanism: A comparison made in the firewall between access in-band qualifiers and access permissions that are programmed in the firewall configuration registers. If the comparison is successful, access is allowed; otherwise, access is denied.
- MCmd qualifier: Command bus that indicates the type of transfer requested. Table 14-1 lists the commands encoded. For information specific to L3_MAIN interconnect error logging, see Table 14-27.

Table 14-1. MCmd Qualifier Description

MCmd[2:0]	Transaction Type
0 0 0	Idle
0 0 1	Write
0 1 0	Read
0 1 1	ReadEx
1 0 0	Read link
1 0 1	Write nonposted
1 1 0	Write conditional
1 1 1	Write broadcast

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- MReqInfo qualifier: Four MReqInfo qualifiers describe the access during the use of the firewall comparison mechanism, as described in Table 14-2.

Table 14-2. MReqInfo Qualifier Description

Qualifiers	Description
MReqType	0: Data access
	1: Opcode fetch
MReqSupervisor	0: User mode
	1: Supervisor mode
MReqDebug	0: Functional access
	1: Debug access

- Register that configures the combination of the MReqInfo, allowing access permission to the target module (TM) based on the MReqInfo in-band qualifier values
- SError: Target that indicates an error condition to the initiator
- SResp qualifier: Response from the target to the initiator concerning the transaction, as described in Table 14-3

Table 14-3. SResp Qualifier Description

SResp[1:0]	Description
0 0	No response
0 1	Data valid/accept
1 0	Not used
1 1	Error

14.1.2 Architecture Overview

The device memory hierarchy includes four levels:

- Level 1 (L1) is internal to the CPUs. The L1 interconnect concerns data exchange with the internal L1 cache memory subsystem, and it is the closest memory to the microprocessor unit (MPU) core and the IVA core.
- Level 2 (L2) is included in the IPU subsystem and the MPU subsystem.
- The chip-level interconnect consists of one L3 interconnect and three L4 interconnects. The chip-level interconnect enables communication among the modules and subsystems in the device.

Figure 14-1 shows an overview of the L3 and L4 interconnect architecture.

PRELIMINARY

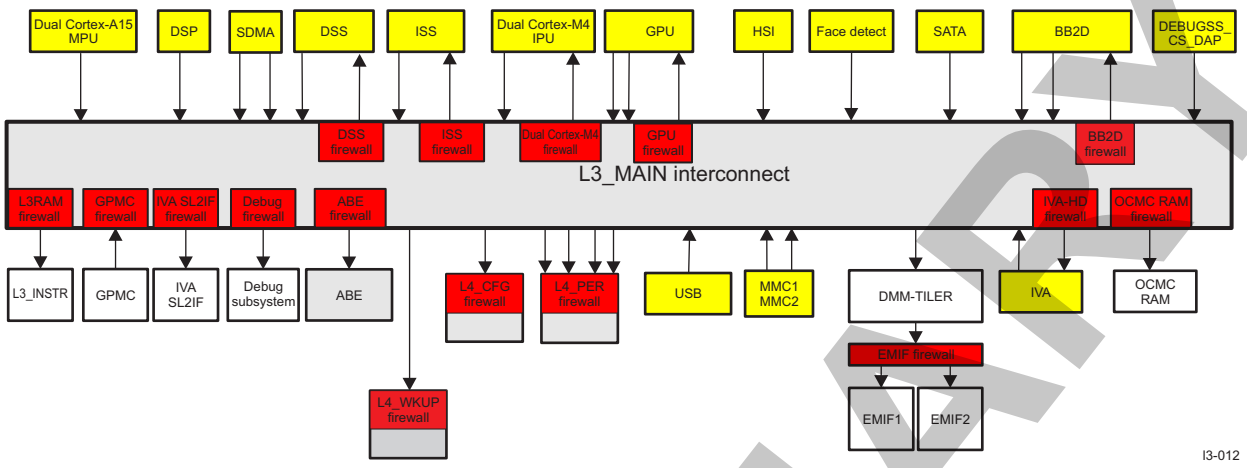
Figure 14-1. Interconnect Overview



- L3_MAIN handles many types of data transfers, especially exchanges with system-on-chip/external memories. L3 transfers data with a maximum width of 128 bits from the initiator to the target. The L3_MAIN interconnect is a little-endian platform
- The L4 is composed of the following:
  - L4_CFG: Includes the majority of the configuration interface for L3 system modules and peripheral interconnect
  - L4_PER: Includes the main peripherals that require system direct memory access (sDMA) access
  - L4_WKUP: Includes peripherals attached to the WKUP power domain

Modules are connected to the interconnect through an IA for the initiator module and a TA for target modules. Each module or subsystem connection is statically configured to tune the access, depending on the characteristics of the module.

To unauthorize a module or L4 interconnect access, some TAs include configurable firewalls (FWs). A firewall restricts or filters the accesses allowed to an initiator according to different access criteria. Software usually configures the firewalls.

The default settings of the L3_MAIN and L4 interconnect are fully functional; they enable all possible functional data paths and a minimal default protection setting. However, the interconnect parameters can be modified to fit user expectations. Interconnect parameters can also be modified by the ROM code for HS/EMU devices.

14.1.3 Module Distribution

IAs and TAs provide the interface to connect the different modules and the interconnect.

Table 14-4 through Table 14-11 list the device modules, subsystems, and associated agents. The agents are listed for each interconnect domain:

- L3_MAIN initiator (master network interface units (NIU) - MN) and target (slave NIUs - SN) agents
- L4_PER initiator and target agents
- L4_CFG initiator and target agents
- L4_WKUP initiator and target agents

14.1.3.1 L3_MAIN Interconnect Module Distribution

Table 14-4 and Table 14-5 list the IAs and TAs, respectively, of the L3_MAIN interconnect.

Table 14-4. Master NIUs

Master NIU	Description
MPU_INIT	Cortex™ A15 MPU subsystem
DSP_INIT	DSP subsystem
IPU_INIT	IPU subsystem
IVA_INIT	Video accelerator subsystem
MMC1_INIT, MMC2_INIT	Multimedia controller
GPU_P1_INIT	3D graphics accelerator port 1
GPU_P2_INIT	3D graphics accelerator port 2
DSS_INIT	Display subsystem
ISS_INIT	Imaging accelerator subsystem
FDIF_INIT	Face detection module
DEBUG_CS_DAP_INIT	JTAG®/emulation access to system resources
SDMA_RD_INIT	System DMA read
SDMA_WR_INIT	System DMA write
HSI_INIT	HSI module
BB2D_P1_INIT	2D graphics accelerator port 1
BB2D_P2_INIT	2D graphics accelerator port 2
USB_HOST_HS_INIT	Multiport USB host controller
USB_OTG_SS_INIT	USB on-the-go controller
SATA_INIT	SATA initiator port

Table 14-5. Slave NIUs

Slave NIU	Description
OCMC_RAM_TARG	On-chip memory controller target port
GPMC_TARG	General-purpose memory controller target port
DMM_P1_TARG	Dynamic memory management target port 1
DMM_P2_TARG	Dynamic memory management target port 2
GPU_TARG	3D graphics accelerator target port
BB2D_TARG	2D graphics accelerator target port
ISS_TARG	Imaging accelerator target port
IVA_CONFIG_TARG	Video accelerator subsystem configuration
IVA_SL2IF_TARG	Video accelerator subsystem shared memory
IPU_TARG	Dual Cortex-M4 subsystem
DSS_TARG	Display subsystem
ABE_TARG	Audio back end (ABE) target port
L3_INSTR_TARG	L3 instrumentation target port
L4_CFG_TARG	L4 interconnect configuration
L4_PER0/1/2/3_TARG	L4 interconnect peripherals
L4_WKUP_TARG	L4 interconnec wakeup
DEBUGSS_CT_TBR_TARG	Debug subsystem target port

14.1.3.2 L4 Interconnect Module Distribution

IAs and TAs provide the interface to connect the different modules to their associated interconnect.

Table 14-6 through Table 14-11 list all modules and subsystems with their associated agents. The agents are listed for each L4 interconnect domain.

PRELIMINARY

14.1.3.2.1 L4_PER Interconnect Agents

The L4_PER interconnect handles transfers only to peripherals in the PER power domain. Table 14-6 lists the PER TAs.

Table 14-6. L4_PER TAs

Module Target Name	Description
UART1_TARG	UART port 1 module
UART2_TARG	UART port 2 module
UART3_TARG	UARTport 3 module
UART4_TARG	UART port 4 module
UART5_TARG	UART port 5 module
UART6_TARG	UART port 6 module
TIMER2_TARG	General-purpose TIMER2 module
TIMER3_TARG	General-purpose TIMER3 module
TIMER4_TARG	General-purpose TIMER4 module
TIMER9_TARG	Genera-purposel TIMER9 module
TIMER10_TARG	General-purpose TIMER10 module
TIMER11_TARG	General-purpose TIMER11 module
GPIO2_TARG	General-purpose input/output 2 (GPIO2) module
GPIO3_TARG	GPIO3 module
GPIO4_TARG	GPIO4 module
GPIO5_TARG	GPIO5 module
GPIO6_TARG	GPIO6 module
GPIO7_TARG	GPIO7 module
GPIO8_TARG	GPIO8 module
I2C1_TARG	Multimaster I2C1 module
I2C2_TARG	Multimaster I2C2 module
I2C3_TARG	Multimaster I2C3 module
I2C4_TARG	Multimaster I2C4 module
I2C5_TARG	Multimaster I2C5 module
MCSPI1_TARG	Multichannel serial port interface controller 1 module
MCSPI2_TARG	Multichannel serial port interface controller 2 module
MCSPI3_TARG	Multichannel serial port interface controller 3 module
MCSPI4_TARG	Multichannel serial port interface controller 4 module
MMC1_TARG	MMC1 module
MMC2_TARG	MMC2 module
MMC3_TARG	MMC3 module
MMC4_TARG	MMC4 module
MMC5_TARG	MMC5 module
ELM_TARG	Error location module
HDQ1W_TARG	HDQ 1-Wire® serial interface controller

Four ports communicate between the L3_MAIN interconnect and the L4_PER interconnect to allow the L3_MAIN initiators to access the L4_PER targets. Table 14-7 lists the L4_PER initiator TAs.

For the list of initiators authorized to access the L4_PER peripherals, see Section 14.2.3.2.2, *Connectivity Matrix*.

14.2 L3 Interconnect

This section describes the L3 interconnect and its components. With the exception of register points, each component includes functions for the request and response networks.

14.2.1 L3_MAIN Interconnect Overview

The L3_MAIN interconnect links cores in a flexible topology that couples low power with high performance. Innovative physical structures and advanced protocols ensure bandwidth and latency to individual IP cores, providing dedicated connections between IP cores and logical connections over a shared interconnect.

The main features of the L3_MAIN interconnects are:

- NIUs: Master NIUs for the IAs and slave NIUs for the TAs
- A partially depleted cross-bar exchange network
- A special internal slave NIU for accessing L3_MAIN interconnect configuration registers
- QoS management for real-time hardware operators, while maintaining optimal memory latency for CPU access to memory resources
- True little-endian platform
- Transaction errors tracking and logging registers
- All signaling support for chip-level power-management infrastructure
- One interrupt line signaling transaction error
- One interrupt line for reporting satistical events on the L3_MAIN interconnect

Figure 14-3 shows an overview of the L3 interconnect and the peripherals attached to it.

14.2.3 L3_MAIN Interconnect Functional Description

14.2.3.1 Module Use in L3_MAIN Interconnect

The L3_MAIN interconnect network components have ConnID values for each master NIU or slave NIU. The ID uniquely identifies the master NIU or the slave NIU for an interconnect transfer. The interconnect uses ConnIDs for a number of purposes, including the following:

- Slave NIUs for error logging
- Power disconnect slave NIU for error logging
- FLAGMUX to mask interrupts: Three, one for each clock domain
- STATCOLL for configuring and monitoring: The STATCOLL components compute the traffic statistics within a user-defined window and periodically report to the user through the debug interface.
- Bandwidth regulator for configuration
- Some rate adapters for configuration of throughput ratio

14.2.3.2 Module Distribution

Master NIUs and slave NIUs provide the interface to connect the different modules to their associated interconnect.

Table 14-15 and Table 14-16 list all the modules and subsystems with their associated agents. The agents are listed for each L3_MAIN interconnect domain.

14.2.3.2.1 L3_MAIN Interconnect Agents

Any initiator or target core is connected to the L3_MAIN interconnect through an NIU. NIUs act as entry points to the L3_MAIN interconnect, and also include various programming registers. Table 14-15 lists the supported master NIU ports.

Table 14-15. Master NIUs

Master NIU	Description
MPU_INIT	Cortex-A15 microprocessor subsystem unit
DSP_INIT	DSP subsystem unit
IPU_INIT	IPU subsystem
IVA_INIT	Video accelerator subsystem

14.2.3.2.2 L3_MAIN Connectivity Matrix

The L3 interconnect is divided into three clock domains:

- L3_CLK1: Low-power domain
- L3_CLK2: Peripherals and multimedia
- L3_CLK3: Instrumentation (debug)

Each clock element is implemented in a different clock domain.

14.2.3.2.2.1 Clock Domain Mapping of the L3_MAIN Interconnect Modules

Each clock domain (CLK1, CLK2, and CLK3) has it own host, flag mux, slave NIUs, and bandwidth regulators. Table 14-17 lists the relationships between these domains and these elements.

Table 14-17. L3_MAIN Clock Domains and Elements

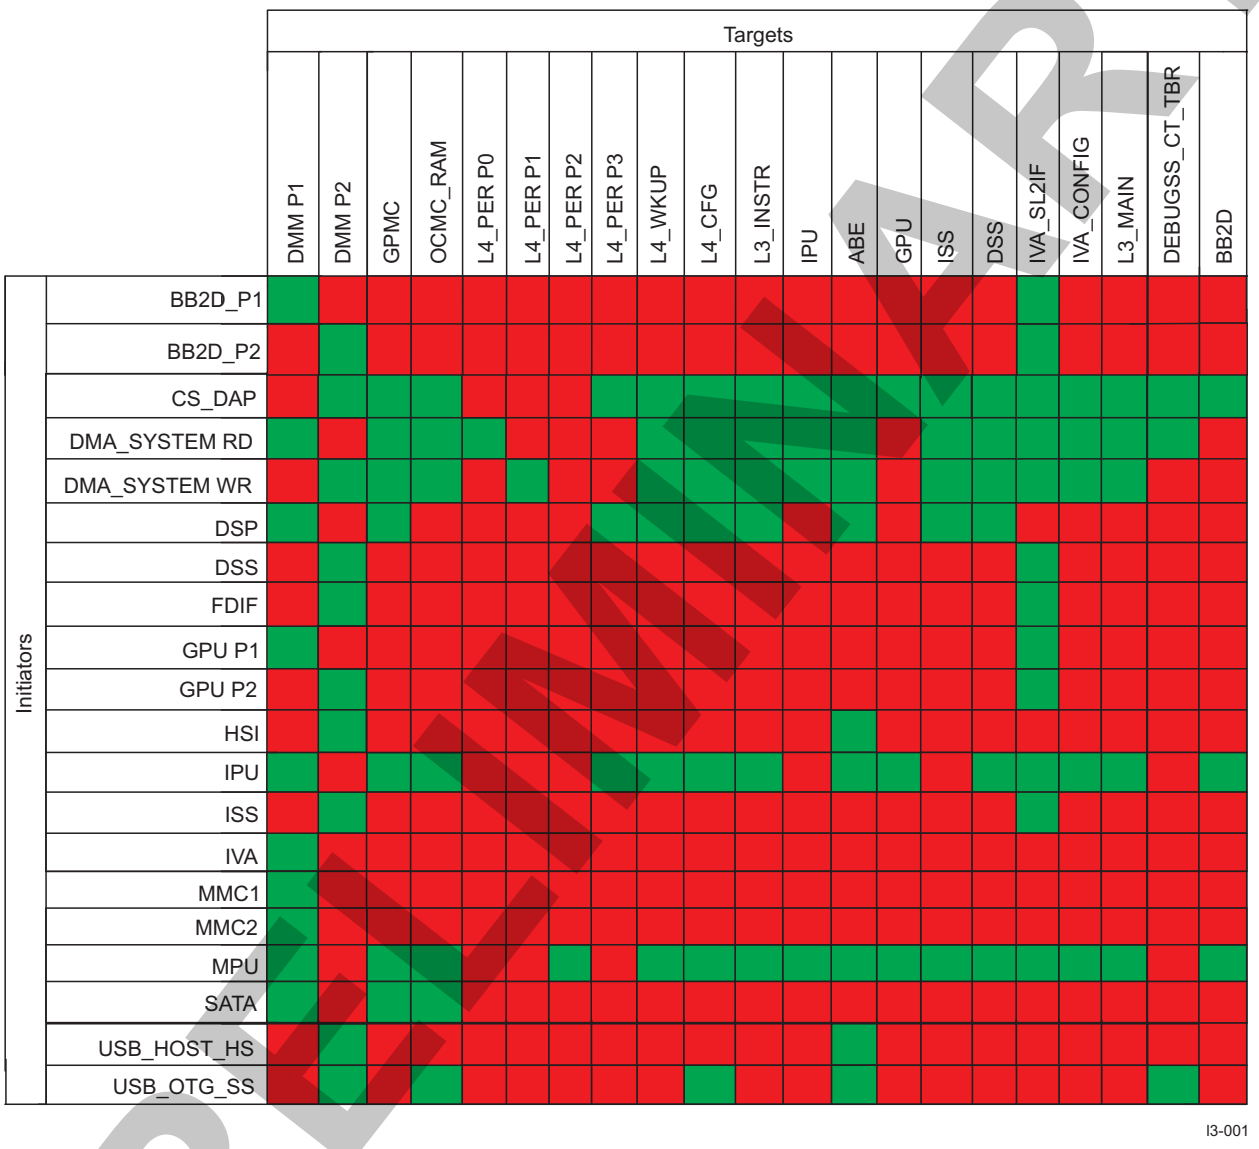
- a cell is red when a functional path does not exist.

Figure 14-4. L3_MAIN Connectivity Matrix



14.2.3.2.3 Master NIU Identification

A master NIU ID (ConnID) is assigned to every module in the device. The ID uniquely identifies the master NIU for an interconnect transfer (see Table 14-18). The interconnect uses ConnID values for a number of purposes, including:

- Master source identification for the protection mechanism
- Response route generation
- Firewall error logging
- L3_MAIN interconnect error logging

14.2.3.3 Bandwidth Regulators

The bandwidth regulators prevent master NIUs from consuming too much bandwidth of a link, or a slave NIU that is shared between several data flows: packets are then transported at a slower rate. The value of a bandwidth can be programmed in the bandwidth regulator. When the bandwidth is below the programmed value, the pressure bit is set to 1, giving priority to this master. When the bandwidth is above the programmed value, the pressure bit is set to 0 and the concerned master has the same weight as others.

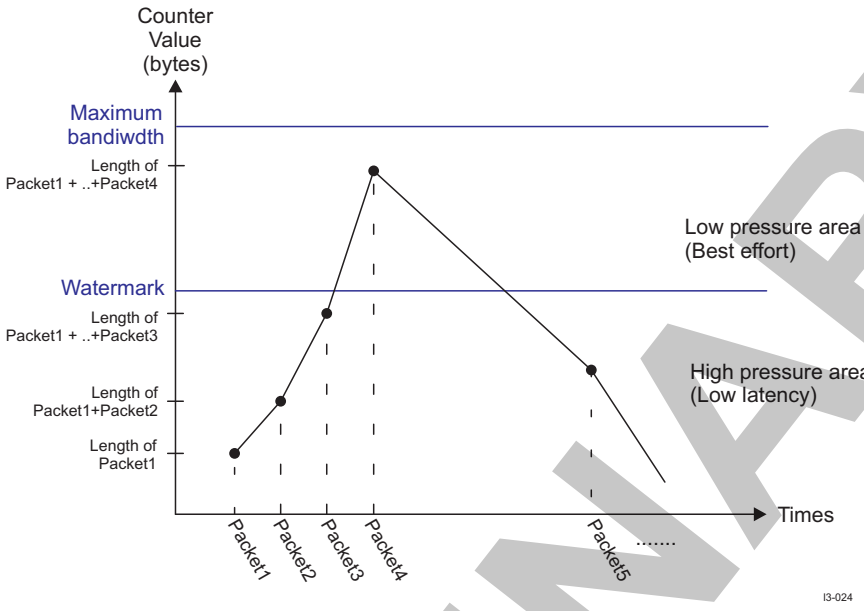
A counter is used to store the sum of data lengths (in bytes) of each packet passing through the bandwidth regulator, and a value equal to the expected bandwidth is subtracted from the counter at each clock cycle. The value of the counter is compared to a programmable threshold (called Watermark), and this comparison determines whether the packet is processed with high pressure for minimum latency or low pressure for best effort processing.

The bandwidth regulator monitors the traffic using open connections between the initiators and the targets. If there is insufficient bandwidth allocated to the connection, the bandwidth regulator can increase the pressure on connections. Generally, the connection is a dataflow between master and slave NIUs. In some cases, the bandwidth regulator is attached to the master and monitors single dataflow to a target (single connection).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 14-5. Bandwidth Regulator Pressure Settings



When Counter Value (bytes) falls below Watermark, the pressure bit is assigned to 1

The bandwidth regulator effective resolution is set to 16.6 MBps. The maximum average bandwidth (max watermark value) computed in a moving window is set to up to 4096 bytes of payload. These settings are implemented by hardware.

The following is an example of bandwidth regulator settings:

The bandwidth regulator is set to run at 200 MHz and the application requires an expected bandwidth of 165.888 MBps (±5 MBps), computed through a moving window of 5 µs (1000 cycles). To attribute high pressure on all packets requests, the watermark could be set to the maximum bandwidth needed in the 5-µs window.

Considering the example, the settings of the bandwidth regulator are:

- L3_BW_R_WATERMARK[11:0] WATERMARK = moving window × expected bandwidth = 829.44 bytes = 0x33D
- L3_BW_R_BANDWIDTH[15:0] BANDWIDTH = 165.888 MBps / effective resolution = 13,271 = 0xD

The bandwidth registers regulate the packet flow by applying flow control on the RX port, thus ensuring that the traffic does not exceed the allocated bandwidth. The next packet is sent only when an internal timer expires. The registers in this group are:

- L3_BW_REGULATOR_WATERMARK: Gives the amount of data allowed to exceed the average bandwidth during a short time period
- L3_BW_REGULATOR_PRESS: Describes the pressure applied to outgoing packets
- L3_BW_REGULATOR_CLEARHISTORY: Resets the traffic counter when set to 1. This register is used after an update in the L3_BW_REGULATOR_BANDWIDTH and L3_BW_REGULATOR_WATERMARK registers (see Section 14.2.5.1.6, *L3 BW Regulator Register Summary and Description*).

Bandwidth regulators are mainly used to give priority to the following masters: IVA, GPU_P1/P2 and BB2D_P1/P2.

As far as DSS and ISS real-time traffic is concerned, its priority is given by internal signal (outputted by the corresponding module). The L3_MAIN interconnect uses this signal to control its internal arbitration.

14.2.3.4 Bandwidth Limiters

The bandwidth limiter is added to control the bandwidth of the BB2D module. This prevents a large number of RD requests being processed together, thus avoiding a large number of RD responses.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The bandwidth limiter regulates the packet flow in the L3_MAIN interconnect by applying flow control when a user-defined bandwidth limit is reached. The next packet is served only after an internal timer expires, thus ensuring that traffic does not exceed the allocated bandwidth.

The registers in this group are:

- L3_BW_LIMITER_WATERMARK_0: Gives the amount of data allowed to exceed the average bandwidth during a short time period. To set the actual watermark to n bytes, the register must be set to n + 1.
- L3_BW_LIMITER_CLEARHISTORY: Resets the traffic counter when set to 1.
- L3_BW_LIMITER_BANDWIDTH_FRACTIONAL and L3_BW_LIMITER_BANDWIDTH_INTEGER: These two registers are used to set the average payload bandwidth.

NOTE: The bandidth limiter is configured to be transparent at reset.

14.2.3.5 Flag Muxing

The flag mux generator collects information such as errors and interrupts from slave NIUs and the interconnect firewall. The result signals are then sent to the MPU interrupt controller (INTC) without interfering with the interconnect traffic. Using the L3_FLAGMUX_MASK registers can prevent the flag mux from seeing certain events.

The unit has a standard COREREG register for identification of the attached core type. The L3_FLAGMUX_STDHOSTHDR_VERSIONREG register identifies the characteristics of the attached core. Use unit-specific registers (MASK bit 0 or bit 1 of the flag inputs, and L3_FLAGMUX_REGERR bit 0 or bit 1) to read the input errors. Each register is dedicated to reporting the bit corresponding to the register number; for example, L3_FLAGMUX_REGERR0 reports on bit 0, and L3_FLAGMUX_REGERR1 reports on bit 1. Any given L3_FLAGMUX_REGERR register reports the same bit for all flag source inputs (see Table 14-164).

14.2.3.5.1 Flag Mux Time-out

If a target does not respond after a fixed number of clock cycles, an error time-out flag is generated, in case it is enabled. The value of the flag is always 3 if a time-out error is present.

To enable time-out for each target, set the L3_FLAGMUX_TIMEOUT_MASK0 register to 1. See Table 14-19.

Table 14-19. L3 Time-out Flag Mapping

	Flag Mux Input	Source
CLK1 Time-out FlagMux	0	L4_WKUP_TARG
	1	L4_CFG_TARG
	2	ABE_TARG
	3	DMM_P2_TARG
	4	DMM_P1_TARG

Table 14-19. L3 Time-out Flag Mapping (continued)

	Flag Mux Input	Source
CLK2 Time-out FlagMux	0	IVA_SL2IF
	1	Reserved
	2	GPU
	3	OCMC_RAM
	5	L4_PER_P3
	6	Reserved
	7	Reserved
	8	L4_PER_P2
	9	L4_PER_P1
	10	L4_PER_P0
	11	IVA_CONFIG
	12	ISS
	13	GPMC
	14	Reserved
	15	Reserved
	16	IPU
	17	BB2D
	18	DSS
CLK3 Time-out FlagMux	0	03_INSTR
	1	DEBUGSS_CT_TBR

For example, to enable all targets in CLK1, write 0x1F in L3_FLAGMUX_TIMEOUT_MASK0. To enable only OCMC_RAM, write 0x8 in L3_FLAGMUX_TIMEOUT_MASK0 (for instance, CLK2_FLAGMUX_CLK2).

If an error time-out occurs, read the L3_FLAGMUX_TIMEOUT_REGERR0 register to check which target does not respond according to Table 14-19.

14.2.3.6 Rate Adapter Generators

The rate adapter generators give the option to configure the L3 interconnect to work in auto-adaptive mode or pipeline mode for sending the packets by using the CNF register. The rate adapter can be configured in store-and-forward mode when the throughput ratio is not well defined, or in auto-adaptive mode when the throughput ratio is predictable. Because the ratios are predictable in the L3_MAIN interconnect, the rate adapters are always used in auto-adaptive mode, except for the rate adapter on the L4_CFG and L4_ ABE responses path. L4_CFG and L4_ABE are configured in store-and-forward mode. The main rate adapt registers are:

- CLK1_RATE_ADAPT_RESP_32TO128_CLK1: Removes WAIT cycles on responses coming from ABE, L4_CFG, and power disconnect to host
- CLK2_RATE_ADAPT_RESP_32TO128_CLK2: Removes WAIT cycles on responses coming from CLK2 32-bit slaves (see Table 14-217)

14.2.3.7 Statistic Collectors Group

Statistic collectors are internal masters that share the same master address as the master NIUs. These components compute the traffic statistics within a defined window and periodically report through the DEBUG interface. The key features of the statistic collector are:

- Nonintrusive monitoring
- Programmable filters and counters
- Collects results at a programmable time interval

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Event detectors are programmed through the L3_STCOL_REQEVT and L3_STCOL_RSPEVT configuration registers for request and response ports, respectively. The following events can be identified:

- Word transfer
- WAIT cycles
- Flow control
- Payload transfers
- Latency measurements

Performance monitoring is enabled through the L3_STCOL_EN register. The L3_STCOL_SOFTEN register enables software to monitor the performance. Event muxes are programmed through the L3_STCOL_EVTMUX_SEL0 configuration register, which determines which port will be monitored by a filter configured by the filter registers (see Table 14-318).

Filters are programmed through the Table 14-318 configuration register, along with additional selection criteria programmed through the mask/match registers (see Table 14-227). A filter can be configured to accept or reject:

- Read operations
- Write operations
- Errors
- Addresses

Filter operation is programmed through the L3_STCOL_OP registers (see Table 14-227).

14.2.3.8 L3_MAIN Protection and Firewalls

Device protection relies on L3 firewalls and their configuration.

14.2.3.8.1 L3_MAIN Firewall Reset

The values of L3_MAIN firewall registers on reset are tied in hardware or exported from the control module registers.

Values exported from the control module are intended to give defined rights to the firewalls at reset and thus ensure the content after going out of reset. Because the control module consists of retention flip-flops (RFFs), which immunize it against register content loss during retention power state, the registers of the control module storing the exported values are not subject to a soft reset.

The L3_MAIN firewall registers are also retention-capable and are immune against content loss during CORE RETENTION power state. The control module registers are reset by a cold reset only, whereas the L3_MAIN firewall registers are reset by clearing the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit. When the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit comes back automatically to 1, the exported values are loaded.

CAUTION

Before reprogramming the firewall registers and/or before using the FW_LOAD_REQ mechanism, the request must be asserted by configuring the REGUPDATE_CONTROL[0] BUSY_REQ bit.

To load the exported values at run time:

1. Set the REGUPDATE_CONTROL[0] BUSY_REQ bit to 0x1 to ensure that no transaction can reach the slave NIU (suspend).
2. Clear the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit by writing 0x1 to it.
3. Wait until the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit is reset to 0x1 by hardware.
4. Set the REGUPDATE_CONTROL[0] BUSY_REQ bit to 0x0 to allow transactions to reach the slave NIU (resume).

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

To reprogram the firewall registers at run time:

1. Set the REGUPDATE_CONTROL[0] BUSY_REQ bit to 0x1 to ensure that no transaction can reach the slave NIU (suspend).
2. Upload the new values to all firewall registers.
3. Set the REGUPDATE_CONTROL[0] BUSY_REQ bit to 0x0 to allow transactions to reach the slave NIU (resume).

NOTE: At reset, exported values from the control module can modify hardware reset values.

14.2.3.8.1.1 L3_MAIN Firewall – Exported Reset Values

Table 14-20 and Table 14-21 list the exported reset values and mapping, respectively.

Table 14-20. L3_MAIN Firewall Exported Reset Values

MRM_PERMISSION_REGION_LOW_j [15:12]	MRM_PERMISSION_REGION_LOW_j [11:0]
0x0	0xFFF
0xF	0xFFF
0x0	0x038
0x2	0x038

[13]	L4_ABE
[16]	BB2D

For more information, see Chapter 18, *Control Module*.

14.2.3.8.2 Power Management

As part of the system-wide power-management scheme, the L3_MAIN interconnect goes into IDLE state after receiving a request from the power, reset, and clock management (PRCM) module after all commands are serviced. This function is handled by hardware.

To reduce power consumption, the L3_MAIN interconnect automatically performs internal clock autogating. This is managed by hardware; no software configurations or settings are required.

Retention is performed on all software-accessible registers:

- Statistic collectors
- Internal rate adapters
- Bandwidth regulators

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- Target agents
- Firewalls

This process prevents reconfiguration after a clock domain switches off.

14.2.3.8.3 L3_MAIN Firewall Functionality

The access to the slave NIUs is granted only to master NIUs according to in-band attributes sent in each transaction crossing the L3_MAIN interconnect, such as:

- MCMD: Specifies the type of access (read or write) required by the master NIU
- ConnID: Used to determine the permission of the master NIU
- MReqInfo: Transaction attribute adding information about the access type

Table 14-22 lists the MReqInfo values.

Table 14-22. MReqInfo Values

Qualifier	Access Definition	Access Description
MReqType	00: Processor data access 01: Processor instruction access 10: DMA access 11: Other	Indicates whether the request is for processor instruction fetch, processor data access or DMA access
MReqDebug	0: Functional 1: Debug	When set, indicates that the request has been issued by a master NIU in DEBUG state
MReqSupervisor	0: User 1: Privilege	When set, indicates that the request is qualified with the supervisor attribute. It can be provided by a processor running in supervisor mode or by a module that inherited this attribute from the processor (DMA channel with a supervisor attribute).

The firewall comparison mechanism enables access to a protected slave NIU only when a correct combination of three MReqInfo in-band parameters is transmitted.

MReqInfo is a combination of a fixed 3-bit pattern that corresponds to a combination of the parameters MReqDebug, MReqType, and MReqSupervisor. See Table 14-23.

14.2.3.8.3.1 Protection Regions

Each slave NIU address space is subdivided into protection regions (maximum of 10). The regions are configurable with a size of 4-KiB granularity. The firewalls can also be multiport while using the description of the same regions for dual-access memories or to support interleaving mechanisms on several memories.

Table 14-24 lists the number of protected regions and ports for each slave NIU.

Table 14-24. Slave NIU Firewall and Region Configuration

Domain	Slave NIU	Firewall	Number of Regions	Number of Ports
CLK1	ABE	ABE_FW	1	1
CLK2	OCMC_RAM	OCMC_RAM_FW	16	1

Two types of regions are distinguished in a slave NIU firewall:

- Default region: Available in all slave NIUs. The default region covers the entire slave NIU address range. Other firewall-configured regions must reset or overlay the default region, because it always has the lowest priority.
- Normal region: The number of normal regions varies in a slave NIU; they have identical capabilities (see Table 14-24).

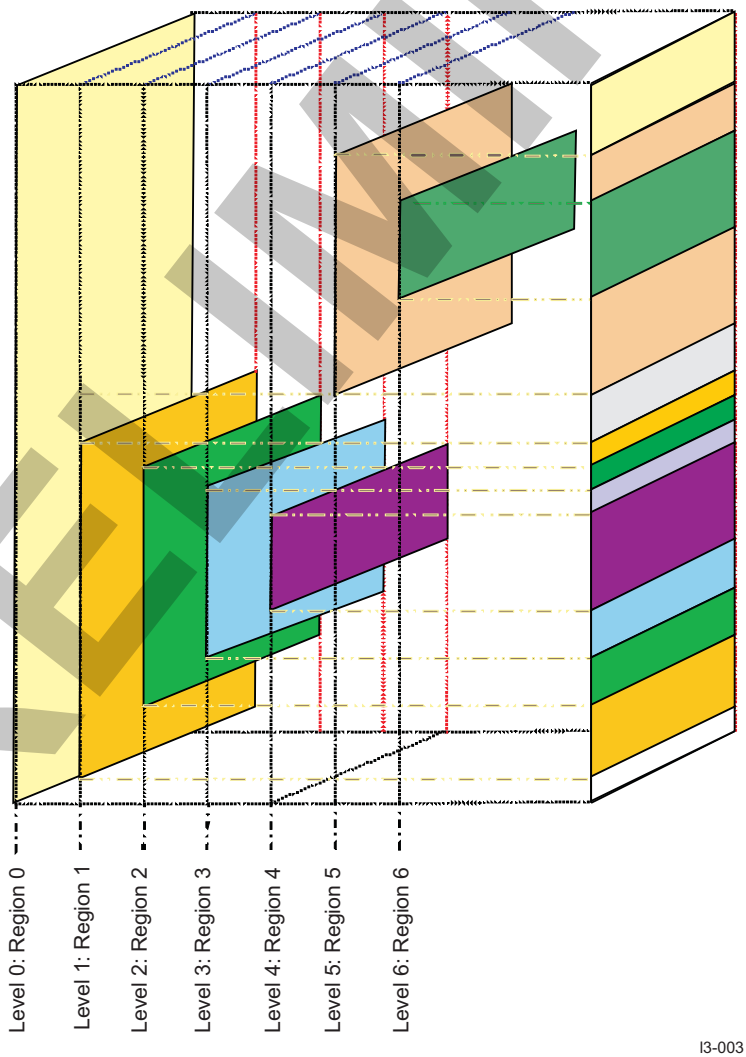
Each region has the following characteristics:

- Start address: Physical slave NIU start address
- End address: Physical slave NIU end address
- Specific access rights (see Section 14.2.3.8.3.3, *Protection Mechanism per Region Examples*)
- Priority level from 0 (lowest) to 10 (highest)

Depending on its priority level, a region can override the settings of another region; the access rights of the region with the highest priority apply. All regions have a fixed (not configurable) priority level that corresponds to their number: Region 1 has priority level 1, region 2 has priority level 2, and so on.

Figure 14-6 shows the priority level with associated regions. This priority level scheme allows multiplying the flexibility and capability of the firewall. Figure 14-6 shows a 7-region firewall setting that creates 13 regions (twice the number of regions created than originally available).

Figure 14-6. L3 Interconnect Region Overlay and Priority Level Overview



PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The address range covered by the regions is defined in the START_REGION_i and END_REGION_i registers. The boundary checks are done on a minimum size of 4-KiB pages; thus, bits [11:0] of those 32-bit registers are not checked.

The address space size of the slave NIUs ([bits [31:12]) depends on the size of the slave NIU to protect (that is, if a memory is only 48KiB, then the size is defined through bits [16:12] of the slave NIU start and end address registers of the firewall region (START_REGION_i[16:12] and END_REGION_i[16:12]).

On multiport firewalls (EMIF), the checking of each REGION {0, n} can activate on one or several ports at the same time. However, if interleaving is not desired on some parts of the protected memory space, it is possible to apply or not apply region checking on selected ports using the region enable/disable on port instance capability of the END_REGION_i register.

Most slave NIUs support only one input port (port 0) except:

- The EMIF module protected by the EMIF firewall has three ports:
  - Port 0 for MPU accesses
  - Port 1 for the first L3_MAIN interconnect accesses
  - Port 2 for the second L3_MAIN interconnect accesses

A region can be applied or not to each port independently. To enable and disable the regions:

- For port 0: Set/clear the END_REGION_i[0] END_REGION_i_ENABLE_CORE0 bit (for all L3_MAIN firewalls).
- For port 1: Set/clear the END_REGION_i[1] END_REGION_i_ENABLE_CORE1 bit (EMIF firewalls).

14.2.3.8.3.2 L3_MAIN Firewall Registers Overview

Table 14-25 and Table 14-26 list the L3_MAIN firewall permission-setting registers.

Table 14-26. L3_MAIN Firewall Permission-Setting Register

Register name	Type of Permission	Bits	Field Name	Description	Field Modifiability
MRM_PERMISSION_REGION_LOW_j	Reserved	31:16		Reserved	
	Debug	15	DEBUG	PUBLIC PRIVILEGE DOMAIN DEBUG ALLOWED	RW
		14	DEBUG	PUBLIC USER DOMAIN DEBUG ALLOWED	RW
	Reserved	13:12		Reserved	
	Access	11	READ	PUBLIC PRIVILEGE READ ACCESS ALLOWED	RW
		10	WRITE	PUBLIC PRIVILEGE WRITE ACCESS ALLOWED	RW
		9	EXE	PUBLIC PRIVILEGE EXE ACCESS ALLOWED	RW
		8	READ	PUBLIC USER READ ACCESS ALLOWED	RW
		7	WRITE	PUBLIC USER WRITE ACCESS ALLOWED	RW
		6	EXE	PUBLIC USER ECXE ACCESS ALLOWED	RW

14.2.3.8.3.3 Protection Mechanism per Region Examples

The access permission of each region is configurable and defined through the MRM_PERMISSION_REGION_HIGH_j and MRM_PERMISSION_REGION_LOW_j registers (see Section 14.2.3.8.3.2, *L3_MAIN Firewall Registers Overview*).

Master NIU permissions:

1. To give read access to the master NIU with ConnID = n, set the MRM_PERMISSION_REGION_HIGH_j[n × 2] R bit.
2. To give write access to the master NIU with ConnID = n, set the MRM_PERMISSION_REGION_HIGH_j[n × 2 + 1] W bit.

Debug permissions:

1. To give privilege debug access, set the MRM_PERMISSION_REGION_LOW_j[15] DEBUG bit.
2. To give user debug access, set the MRM_PERMISSION_REGION_LOW_j[14] DEBUG bit.

User, read, write, and executable permissions:

1. To give privileged write access, set the MRM_PERMISSION_REGION_LOW_j[11] READ bit.
2. To give privileged read access, set the MRM_PERMISSION_REGION_LOW_j[10] WRITE bit.
3. To give privileged executable access, set the MRM_PERMISSION_REGION_LOW_j[9] EXE bit.
4. To give user write access, set the MRM_PERMISSION_REGION_LOW_j[8] READ bit.
5. To give user read access, set the MRM_PERMISSION_REGION_LOW_j[7] WRITE bit.
6. To give user executable access, set the MRM_PERMISSION_REGION_LOW_j[6] EXE bit.

Example: To provide debug write privilege access to the master NIU ConnID = 7, set the following bits:

- MRM_PERMISSION_REGION_HIGH_j[15] W
- MRM_PERMISSION_REGION_LOW_j[15] DEBUG

14.2.3.8.3.4 L3_MAIN Firewall Error Logging

If a protection violation error is detected, the following signals are generated:

- An in-band error is generated to the master NIU of the access.
- An interrupt is generated to the Cortex-A15 and DSP INTCs.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The L3_MAIN interconnect does not differentiate errors generated by firewalls from all other supported types of errors.

An in-band error is generated by modules each time an access is not allowed. When an in-band error is sent back into the transaction it is seen as an external prefetch or data abort by the initiator, depending on whether the transaction was an instruction fetch or a data access.

Information about in-band errors is logged into two registers:

- ERROR_LOG_k: Logs the information about the start/end address of the hit region and the qualifiers of the transaction
- LOGICAL_PHYSICAL_ADDRESS_ERRLOG_k[31:12]: Logs the address of the failed access

NOTE: When a multiport firewall is implemented, these registers are duplicated for each port.

Table 14-27 lists the L3_MAIN firewall error-logging registers.

Table 14-27. L3 Firewall Error-Logging Registers

Register Name	Register Field Name	Field Modifiability	Parameter Comments
ERROR_LOG (When multiport firewall is implemented the error log register is duplicated for each port.)	RESERVED[31:24]	Read only	Reads return 0s.
	BLK_BURST_VIOLATION[23]	Read/write	Read 0x1: 2D burst not allowed or exceeds allowed size. Write to clear the ERROR_LOG and LOGICAL_PHYSICAL_ADDRESS_ERRLOG registers.
	SLVOFST_TRANSLATION_VIOLATION[22]	Read/write	START and END address of translated region cross two regions Marked as reserved when translation mechanism is not generated
	REGION_START_ERRLOG[21:17]	Read/write	Read: Wrong access hit this region number. Write to clear the ERROR_LOG and LOGICAL_PHYSICAL_ADDRESS_ERRLOG registers.
	REGION_END_ERRLOG[16:12]	Read/write	Read: Wrong access hit this region number. Write to clear the ERROR_LOG and LOGICAL_PHYSICAL_ADDRESS_ERRLOG registers.
	REQINFO_ERRLOG[11:0]	Read/write	Mapping of the error according to the reqinfo vector: ConnID [3:0] MCMD [0] [3] MReqDebug [1] MReqSupervisor [0] MReqType

L3 firewall errors can be cleared by writing to the ERROR_LOG_k register in the firewall that recorded the error. Clearing the ERROR_LOG_k register deasserts the corresponding error if it exists.

The L3 firewall register ERROR_LOG_k must be cleared before clearing the CONTROL_CORE_SEC_ERR_STATUS_FUNC and CONTROL_CORE_SEC_ERR_STATUS_DEBUG registers in the control module.

When a protection violation occurs, an interrupt is sent to the MPU and DSP INTC (if enabled). An in-band error is sent back, and an error is logged in the CONTROL_SEC_ERR_STATUS_FUNC and CONTROL_SEC_ERR_STATUS_DEBUG registers, depending on the functional mode:

- In application mode:
  - CONTROL_SEC_ERR_STATUS_FUNC[1] – L3 RAM protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[2] – GPMC protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[3] – EMIF protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[4] – IVA protection violation

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

- CONTROL_SEC_ERR_STATUS_FUNC[5] – IPU protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[6] – IVA SL2 protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[8] – SYSTEM DMA protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[13] – GPU protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[14] – DSS protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[15] – ISS protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[16] – L4_PER protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[17] – L4_CFG protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[18] – DEBUG subsystem protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[19] – AUDIO slave NIU protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[22] – L4_WKUP protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[23] – BB2D protection violation

• In debug mode:

- CONTROL_SEC_ERR_STATUS_DEBUG[1] – L3 RAM protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[2] – GPMC protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[3] – EMIF protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[4] – IVA protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[5] – IPU protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[6] – IVA SL2 protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[13] – GPU protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[14] – DSS protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[15] – ISS protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[16] – L4_PER protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[17] – L4_CFG protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[18] – DEBUG subsystem protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[19] – AUDIO slave NIU protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[22] – L4_WKUP protection violation
- CONTROL_SEC_ERR_STATUS_BEGUG[23] – BB2D protection violation

For more information, see Chapter 18, *Control Module*.

14.2.3.8.3.5 L3_MAIN Firewall Default Configuration

Table 14-28 summarizes the configuration of the L3_MAIN firewalls.

Table 14-28. L3_MAIN Firewalls Default Configurations

Device/Region: 0

11	EMIF firewall	Regions 1 to 7

14.2.3.9 L3_MAIN Interconnect Error Handling

Error logging is enabled in the L3_MAIN interconnect. The three major types of errors are:

- Slave NIU errors
- Firewall errors (see Section 14.2.3.8.3.4, *L3_MAIN Firewall Error Logging*)
- Flag mux errors

14.2.3.9.1 Global Error-Routing Scheme

Figure 14-7 shows the L3_MAIN global error-routing scheme.

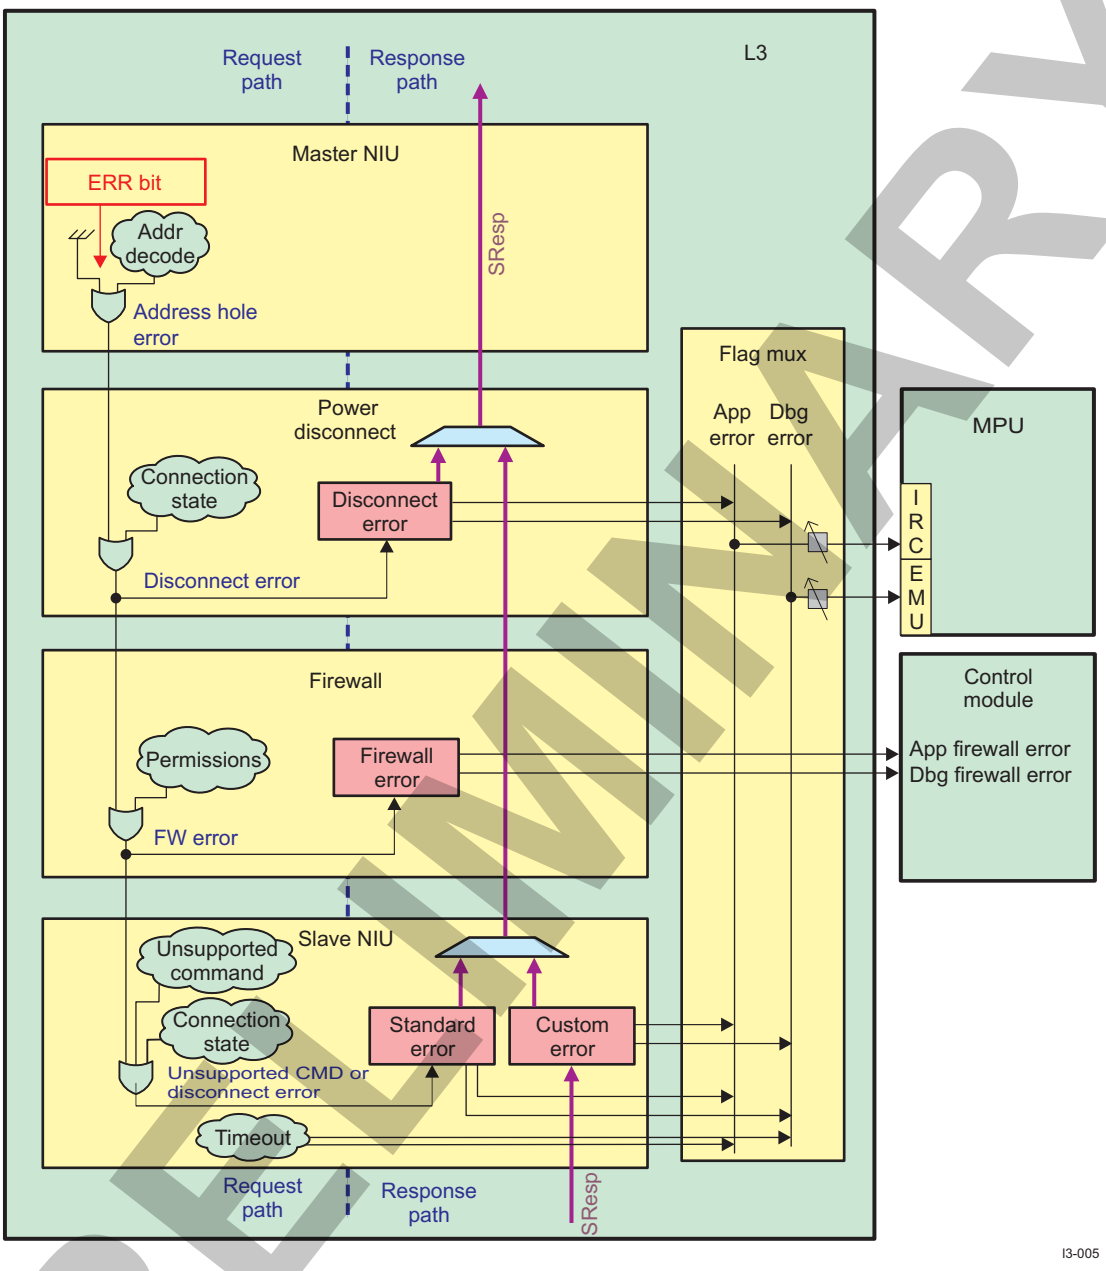
Figure 14-7. L3_MAIN Global Error-Routing Scheme



14.2.3.9.2 Slave NIU Error Logging

Error logging is implemented only at slave NIUs. Because the interconnect does not support master NIU error logging, an erroneous packet must be created and sent to one of the slave NIUs. The slave NIU that receives an erroneous packet is predictable but can change per master (see Table 14-30).

Table 14-30. L3_MAIN Connectivity and Holes Error Routing

Master	Connectivity and Holes Errors Logged Into Slave NIUs
DEBUGSS_CS_DAP	GPMC
IPU	
MPU	
DMA_SYSTEM_RD	
DMA_SYSTEM_WR	
SATA	
DSP	
IVA	DMM1
MMC1	
MMC2	
BB2D_P1	
GPU_P1	
DSS	
	ISS
	FACDMM2ECT
	BB2D_P2
	GPU_P2
USB_OTG_SS	OCMC_RAM
HSI	ABE
USB_HOST_HS	

The slave NIU can be configured to report standard errors (errors generated within the interconnect):

- Firewall error: Protection violation; this error indicates that a request was rejected by a firewall and is reported to the control module. For more information, see Section 14.2.3.8.3.4, *L3_MAIN Firewall Error Logging*.
- Address hole: This error reports an unknown address for a request. The address map is local to each master NIU; therefore, an address hole error is reported each time a master NIU requests an access to a slave NIU to which it is not logically connected, even if this address exists in the global L3_MAIN address map. This error is detected only once per burst.
- Unsupported commands: This error reports that the master NIU sent a command that cannot be processed, because the slave NIU cannot accept it and no conversion to another command is possible. This error is detected only once per burst.
- Report custom errors: Basically, when the slave answer is SResp = ERR
- Report severity level, for standard error and custom errors:
  - None: Error logging for this type of error is disabled.
  - Error: Error is logged for this type of error.
  - Fault: Error is logged and interrupt is generated for this type of error.
- Generate interrupt on 2 bits depending on the MReqDebug qualifier:
  - Application error - FAULT[0]
  - Debug error - FAULT[1]

  By default, all slave NIUs are configured with standard and custom error levels set to FAULT. The errors are reported on the two flag muxes (see Figure 14-7), depending on the access type, application or debug. For more information, see Section 14.2.3.9.3, *Flag Mux Error Logging*.

  The slave NIU power-disconnect component also has error logging enabled, because in this case the slave NIU is in a clock domain that is switched off and therefore cannot catch the error. By nature, this component can generate only standard errors. By default, it is configured with the error level set to FAULT.

  Wake up on demand: If an error packet reaches a slave NIU that is set with MDiscBehave = 1 (wake up on demand), then the active signal is asserted and L3 processes the error generation when the

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

slave is awake. Although this is inefficient, it simplifies NIU implementation and should not be a problem because errors are supposed to occur only during software debug.

14.2.3.9.3 Flag Mux Error Logging

All fault signals are sent to a flag mux component. There are four important FLAGMUX registers:

- L3_FLAGMUX_MASK0: Masks application error sources
- L3_FLAGMUX_MASK1: Masks debug error sources
- L3_FLAGMUX_REGERR0: Checks which application error sources are active
- L3_FLAGMUX_REGERR1: Checks which debug error sources are active

The two L3_FLAGMUX_MASK registers mask bit 0 or bit 1 of the flag inputs, and the L3_FLAGMUX_REGERR registers read input errors. Each register is dedicated to reporting the bit corresponding to the register number.

Table 14-31 describes the mapping of the flags to the corresponding sources.

Table 14-31. Interconnect Flag Mapping

	Flag Mux Input	Source
CLK1 Flag Mux	0	DMM_P1
	1	DMM_P2
	2	ABE
	3	L4_CFG
	4	CLK1_PWR_DISC_TARG_CLK2
	5	HOST_CLK1
	6	L4_WKUP
CLK2 Flag Mux	0	IPU
	1	DSS

	3	ISS
	4	IVA_CONFIG
	6	L4_PER_P0
	7	OCMC_RAM
	8	GPMC SERROR
	9	GPU
	10	IVA_SL2IF
	12	CLK2_PWR_DISC_TARG_CLK1
	15	L4_PER_P3
	16	L4_PER_P1
	17	L4_PER_P2
	18	HOST_CLK2
	22	BB2D
CLK3 Flag Mux	0	L3_INSTR
	1	DEBUGSS_CT_TBR
	2	HOST_CLK3

14.2.3.9.4 Severity Level of Standard and Custom Errors

The slave NIU registers are important for error logging.

- The L3_TARG_STDERRLOG_SVRTSTDLVL register shows the severity level for standard errors. According to the severity level, error logging is disabled, enabled with level ERROR, or enabled with level ERROR and flag FAULT.
- The L3_TARG_STDERRLOG_SVRTCUSTOMLVL register shows the severity level for custom errors

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

(see Table 14-69).

- The L3_TARG_STDERRLOG_MAIN register (the main register for error-logging management) shows the validity of the logged information, standard or custom.
- The L3_TARG_STDERRLOG_HDR register stores packets in case of a standard error.
- The L3_TARG_STDERRLOG_MSTADDR register returns the MSTADDR field of the logged packet.
- The L3_TARG_STDERRLOG_SLVADDR register returns the SLVADDR field of the stored packet.
- The L3_TARG_STDERRLOG_INFO register saves the information field of the logged packet.

14.2.4 L3_MAIN Interconnect Programming Guide

14.2.4.1 L3 _MAIN Interconnect Low-Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L3_MAIN interconnect module.

14.2.4.1.1 Global Initialization

14.2.4.1.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the L3_MAIN interconnect module is to be used for the first time after a device reset. The initialization of surrounding modules is based on the integration and environment of the L3_MAIN interconnect. For more information, see Section 14.2.2, *L3_MAIN Interconnect Integration* .

Table 14-32. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	For information about the configuration of the PRCM module, see Chapter 3, *Power, Reset, and Clock Management*.
Control module	For information about the configuration of the control module, see Chapter 18, *Control Module*.
MPU INTC	The MPU INTC must be configured to enable interrupts from the L3 interconnect module. See Chapter 17, *Interrupt Controllers*.
sDMA	For information about the configuration of the sDMA, see Chapter 16, *sDMA*.
L3 interconnect	For information about the configuration of the interconnect, see Chapter 14, *Interconnect*.

14.2.4.2 Operational Modes Configuration

14.2.4.2.1 L3_MAIN Interconnect Error Analysis Mode

14.2.4.2.1.1 Main Sequence: L3_MAIN Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

Figure 14-8 shows the software sequence required in most cases.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 14-8. Typical Error Analysis Sequence

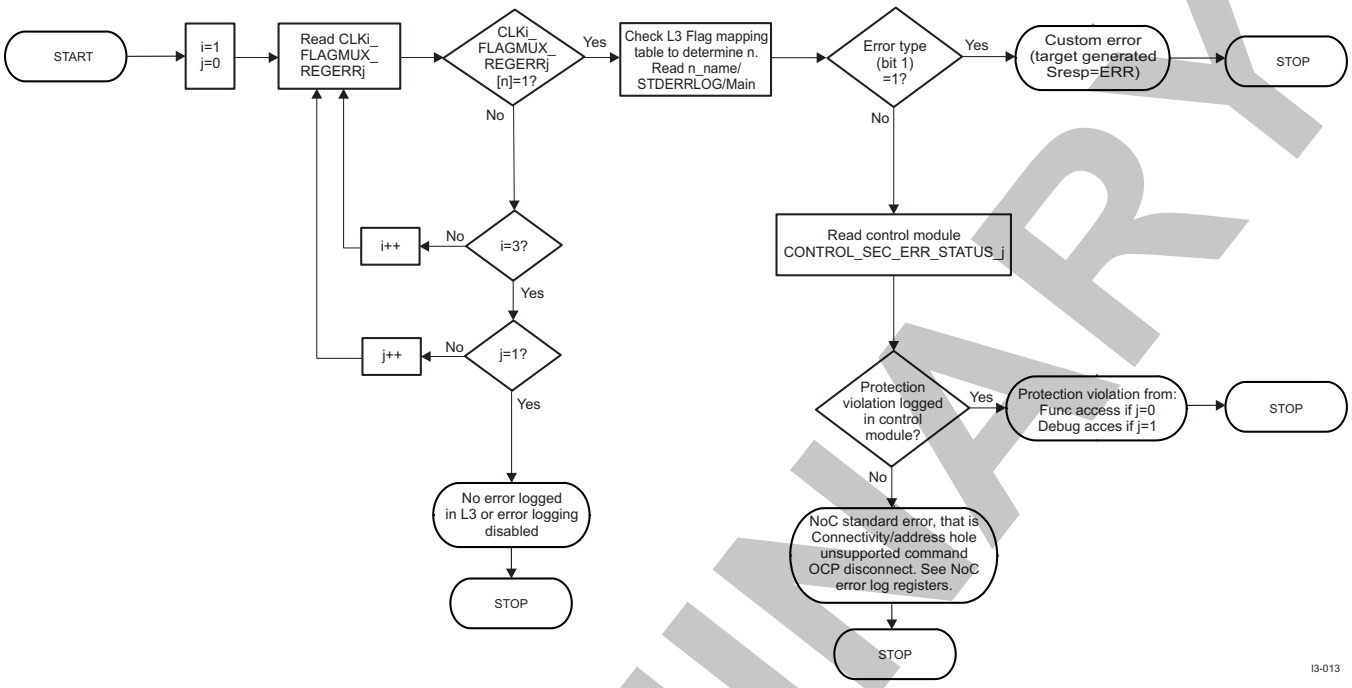

Table 14-33 lists the subprocess call summary for error analysis mode in the main sequence.

Table 14-33. Subprocess Call Summary for Main Sequence – Error Analysis Mode

Subprocess	Cross-Reference
L3 interconnect error analysis	See Section 14.2.4.2.1, *L3_MAIN Interconnect Error Analysis Mode.*
L3_MAIN interconnect protection violation error identification	See Section 14.2.4.2.1.1.2, *Subsequence: L3_MAIN Interconnect Protection Violation Error Identification.*
L3_MAIN interconnect unsupported command/address hole error identification	See Section 14.2.4.2.1.1.3, *Subsequence: L3_MAIN Interconnect Standard Error Identification.*
L3_MAIN interconnect reset FLAGMUX and module	See Section 14.2.4.2.1.1.4, *Subsequence: L3_MAIN Interconnect FLAGMUX Configuration.*

14.2.4.2.1.1.1 Subsequence: L3_MAIN Custom Error Identification

The procedure listed in Table 14-34 describes custom error identification.

Table 14-34. Custom Error Identification

Step	Register/Bit Field/Programming Model	Value
IF: Is custom error detected?	L3_TARG_STDERRLOG_MAIN[1] STDERRLOG_MAIN_ERRTYPE	=0x1
Read information field of the response packet.	L3_TARG_STDERRLOG_CUSTOMINFO_INFO[7:0] STDERRLOG_CUSTOMINFO_INFO	xxx
Read the address of the initiator that caused error.	L3_TARG_STDERRLOG_CUSTOMINFO_MSTADDR[10:0] STDERRLOG_CUSTOMINFO_MSTADDR	xxx
Read the type of operation (read/write).	L3_TARG_STDERRLOG_CUSTOMINFO_OPCODE[1:0] STDERRLOG_CUSTOMINFO_OPCODE	xxx
ENDIF

14.2.4.2.1.1.2 Subsequence: L3_MAIN Interconnect Protection Violation Error Identification

The procedure listed in Table 14-35 describes protection violation error identification and where it is logged in the control module registers. Two types of errors are logged: application errors and debug errors.

Table 14-35. L3_MAIN Protection Violation Error Identification

Step	Register/Bit Field/Programming Model	Value
Read the burst violation.	ERROR_LOG_k[23] 2D_BURST_VIOLATION	xxx
Read the initiator ID.	ERROR_LOG_k[3:0] ConnID	xxx
Read the command that caused the error.	ERROR_LOG_k[7] MCMD	xxx
Read the address of the request that caused the error.	ERROR_LOG_k[31:12] SLVOFS_LOGICAL	xxx
IF: Is it an application error?	L3_FLAGMUX_REGERR0 [7:0] REGERROR0	0x0
Read the status bits to see which module firewall has worked.	CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[20:0]	xxx
Clear the status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[20:0]	xxx
Clear the status bit.	L3_TARG_STDERRLOG_MAIN [31] STDERRLOG_MAIN_CLRLOG	0x0
ELSE IF	L3_FLAGMUX_REGERR1[7:0] REGERROR1	= 0x1
Read the status bits to see the module.	CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[20:0]	xxx
Clear the status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[20:0]	xxx
Clear the status bit.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG	0x0
ENDIF		
Clear the burst violation.	ERROR_LOG_k[23] 2D_BURST_VIOLATION	0x0
Clear the error status.	ERROR_LOG_k[21:17] REGION_START_ERRLOG	0x00

14.2.4.2.1.1.3 Subsequence: L3_MAIN Interconnect Standard Error Identification

The procedure listed in Table 14-36 describes the identification of standard errors inside the L3_MAIN interconnect. The standard errors are: unsupported command, address hole, and disconnect.

Table 14-36. L3_MAIN Standard Error Identification

Step	Register/Bit Field/Programming Model	Value
IF: Is an error detected?	L3_TARG_STDERRLOG_MAIN[18] STDERRLOG_MAIN_ERRCNT	= 0x1
Read the corresponding flag.	L3_FLAGMUX_REGERR0[7:0] REGERROR0	xxx
Read the corresponding flag.	L3_FLAGMUX_REGERR1[7:0] REGERROR1	xxx
Localize the slave NIU that generated the error.	See Table 14-31.	
ELSE		
Clear the error log.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG	0x0
Clear the severity error status.	L3_TARG_STDERRLOG_SVRTSTDLVL[1:0] STDERRLOG_SVRTSTDLVL_0	0x2
ENDIF		

14.2.4.2.1.1.4 Subsequence: L3_MAIN Interconnect FLAGMUX Configuration

The procedures listed in Table 14-37 and Table 14-38 give information about the configuration of FLAGMUX masks.

PRELIMINARY

14.2.5 L3_MAIN Interconnect Register Manual

14.2.5.1 L3_MAIN Register Group Summary

The registers in the L3 interconnect are divided into eight groups:

- Firewall registers (see Table 14-40)
- HOST registers (see Table 14-62)
- TARG registers (see Table 14-98)
- PWR_DISC registers (see Table 14-141)
- FLAGMUX registers (see Table 14-165)
- BW registers (see Table 14-188)
- RA registers (see Table 14-218)
- STATCOLL registers (see Table 14-227)

14.2.5.1.1 L3_MAIN Firewall Registers Summary and Description

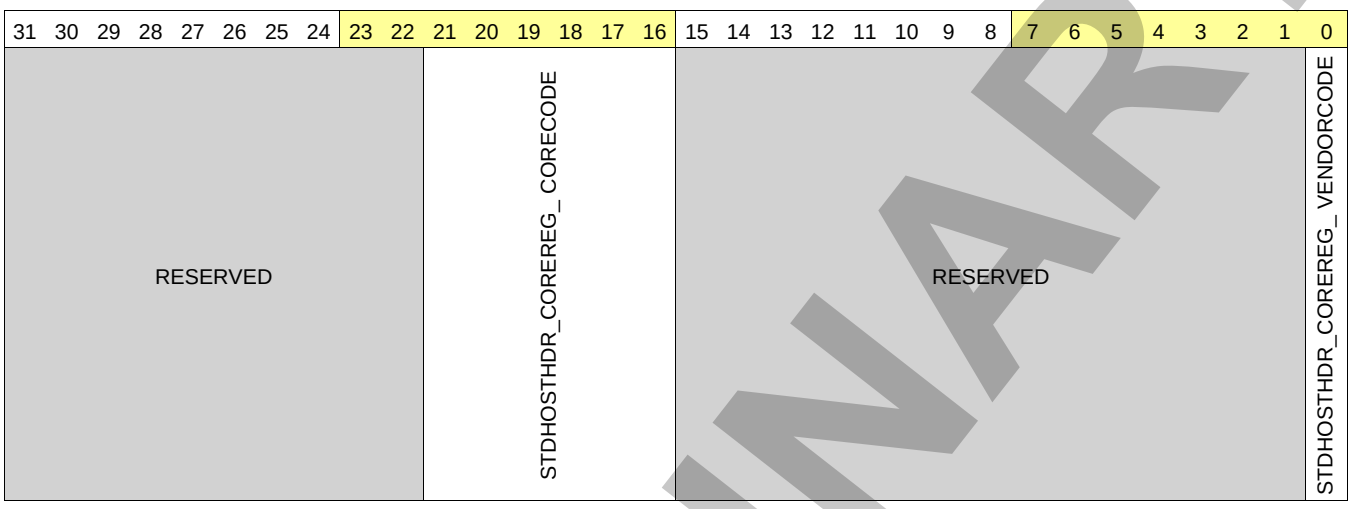
Table 14-106. L3_TARG_STDHOSTHDR_COREREG

Address Offset	See Table 14-98.	**Index**	
Physical Address	See Table 14-98 to Table 14-105	**Instance**	See Table 14-98 to Table 14-105
Description			
Type	R		



Bits	Field Name	Description	Type	Reset
31:22	RESERVED		R	0x000
21:16	STDHOSTHDR_COREREG_ CORECODE	The Core Code field is a constant reporting a vendor-specific core generator code. Type: Constant. Reset value: 0x13.	R	0x13
15:1	RESERVED		R	0x0000
0	STDHOSTHDR_COREREG_ VENDORCODE	The Vendor Code field is a constant reporting the core generator vendor code. Type: Constant. Reset value: 0x1. Read 0x0: Third-party vendor. Read 0x1:	R	1

Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												STDHOSTHDR_MAINCTLREG_CM	STDHOSTHDR_MAINCTLREG_FLT	RESERVED	STDHOSTHDR_MAINCTLREG_EN

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Reserved	R	0x0000000
3	STDHOSTHDR_MAINCTLREG_CM	Reserved for internal testing. Must be set to 0. Type: Control. Reset value: 0x0.	R	0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
2	STDHOSTHDR_MAINCTLREG_FLT	Asserted when a Fault condition is detected: if the unit includes Error Logging, Flt is asserted when the FltCnt register field indicates a Fault, and deasserted when FltCnt is reset. If no Error Logging is implemented, this bit becomes unit-dependent. In all cases, Flt bit and Flt pin (service network) have the same logical level. Type: Status. Reset value: X.	R	0
1	RESERVED	Reserved	R	0
0	STDHOSTHDR_MAINCTLREG_EN	Sets the global core enable. Note: A disabled master does not generate any NTTP requests, and a disabled slave replies with an error packet to any request it receives. Type: Control. Reset value: 0x1.	RW	1

14.3 L4 Interconnects

This section details the device L4 interconnects.

14.3.1 L4 Interconnect Overview

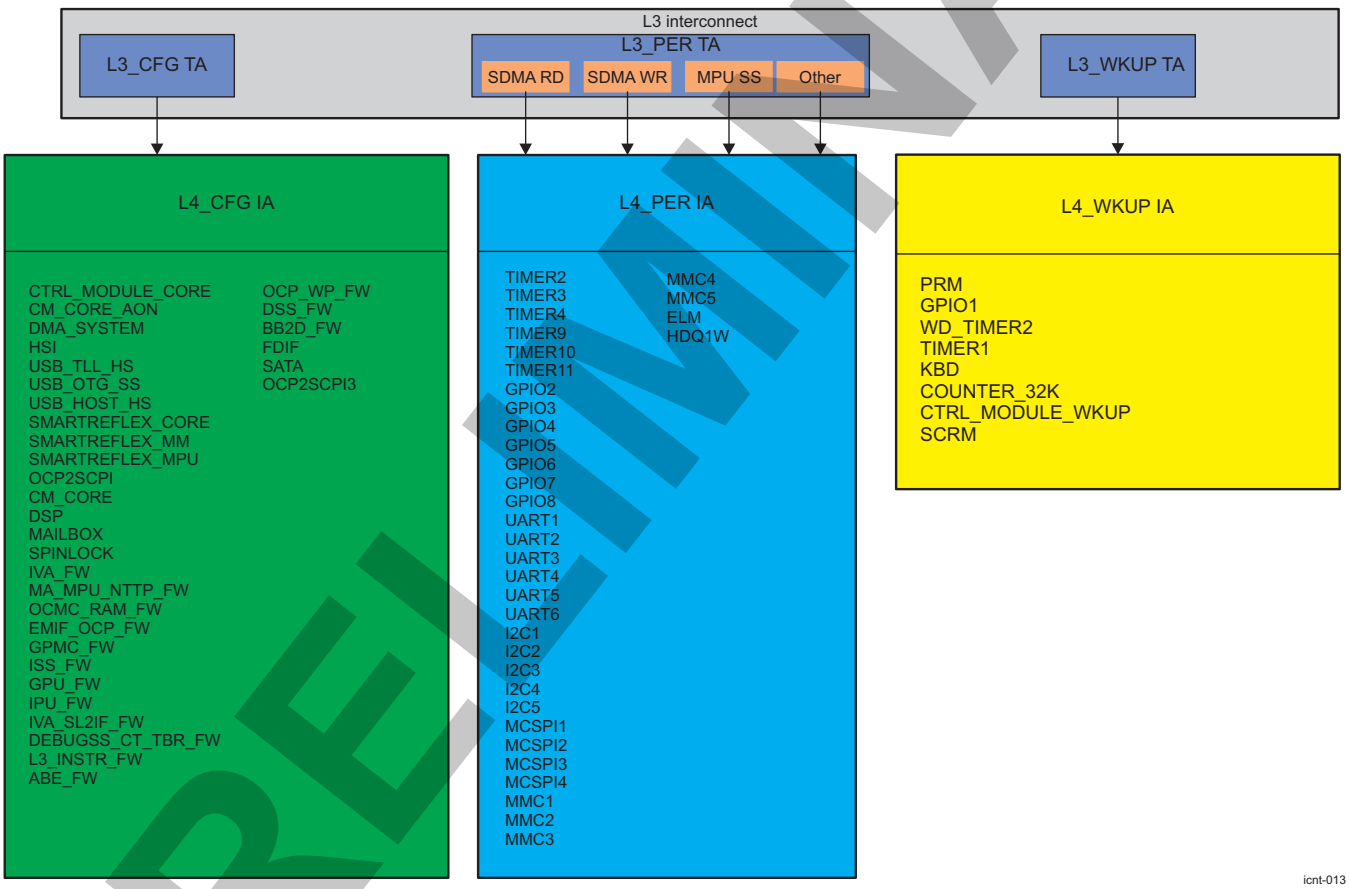
The device uses three separate L4 interconnect structures to connect peripheral modules. All L4s handle transfers with peripherals but are located in distinct power domains.

Figure 14-9 is an overview of the L4 interconnects and the peripherals attached to them.

The L4 interconnect is composed of the following interconnects:

- L4_CFG: Includes the majority of the configuration interface for L3_MAIN system modules and peripheral interconnect
- L4_PER: Includes the main peripherals that require sDMA access
- L4_WKUP: Includes peripherals attached to the WKUP power domain

Figure 14-9. L4 Interconnect Overview



The main features of the L4 interconnects are:

- Six ports from L3 interconnect onto three parallel L4 interconnects
- From one to four 32-bit initiator ports for each L4 interconnect instance
- 8-, 16-, or 32-bit data, single, or burst transactions
- Little-endian platform
- Nonblocking architecture with fair arbitration between threads
- Target interfaces: Fully synchronous or divided synchronous
- L4_CFG and L4_PER frequency equal half of L3 frequency
- Protection logic that provides user-configurable access control to targets by each initiator

14.3.3 L4 Interconnect Functional Description

14.3.3.1 Module Distribution

IAs and TAs provide the interface to connect the different modules to their associated interconnect.

Table 14-370 through Table 14-375 list all the modules and subsystems with their associated agents. The agents are listed for each L4 interconnect domain.

14.3.3.1.1 L4_PER Interconnect Agents

The L4_PER interconnect handles transfers only to peripherals in the PER power domain. Table 14-370 lists the L4_PER TAs.

Table 14-370. L4_PER TAs

Module Target Name	Description
UART1_TARG	UART port 1 module
UART2_TARG	UART port 2 module

Table 14-375. L4_WKUP IAs

Module Iniator Name	Description
L3_MAIN_INIT	L3 interconnect port

14.3.3.2 Power Management

As part of the system-wide power-management scheme, the L4 interconnects go into IDLE state after receiving a request from the PRCM module after all commands are serviced. This function is handled by hardware. For more information, see Section 3.1.1, *Power, Reset, and Clock Management*.

To reduce power consumption, each L4 interconnect automatically performs internal clock autogating. This is managed by hardware; no software configurations or settings are required.

Retention is performed on all software-accessible registers at IAs, TAs, and firewalls. This process prevents reconfiguration after a clock domain switches off. For more information, see Section 3.1.1.2, *Power Management*, in Section 3.1.1, *Power, Reset, and Clock Management*.

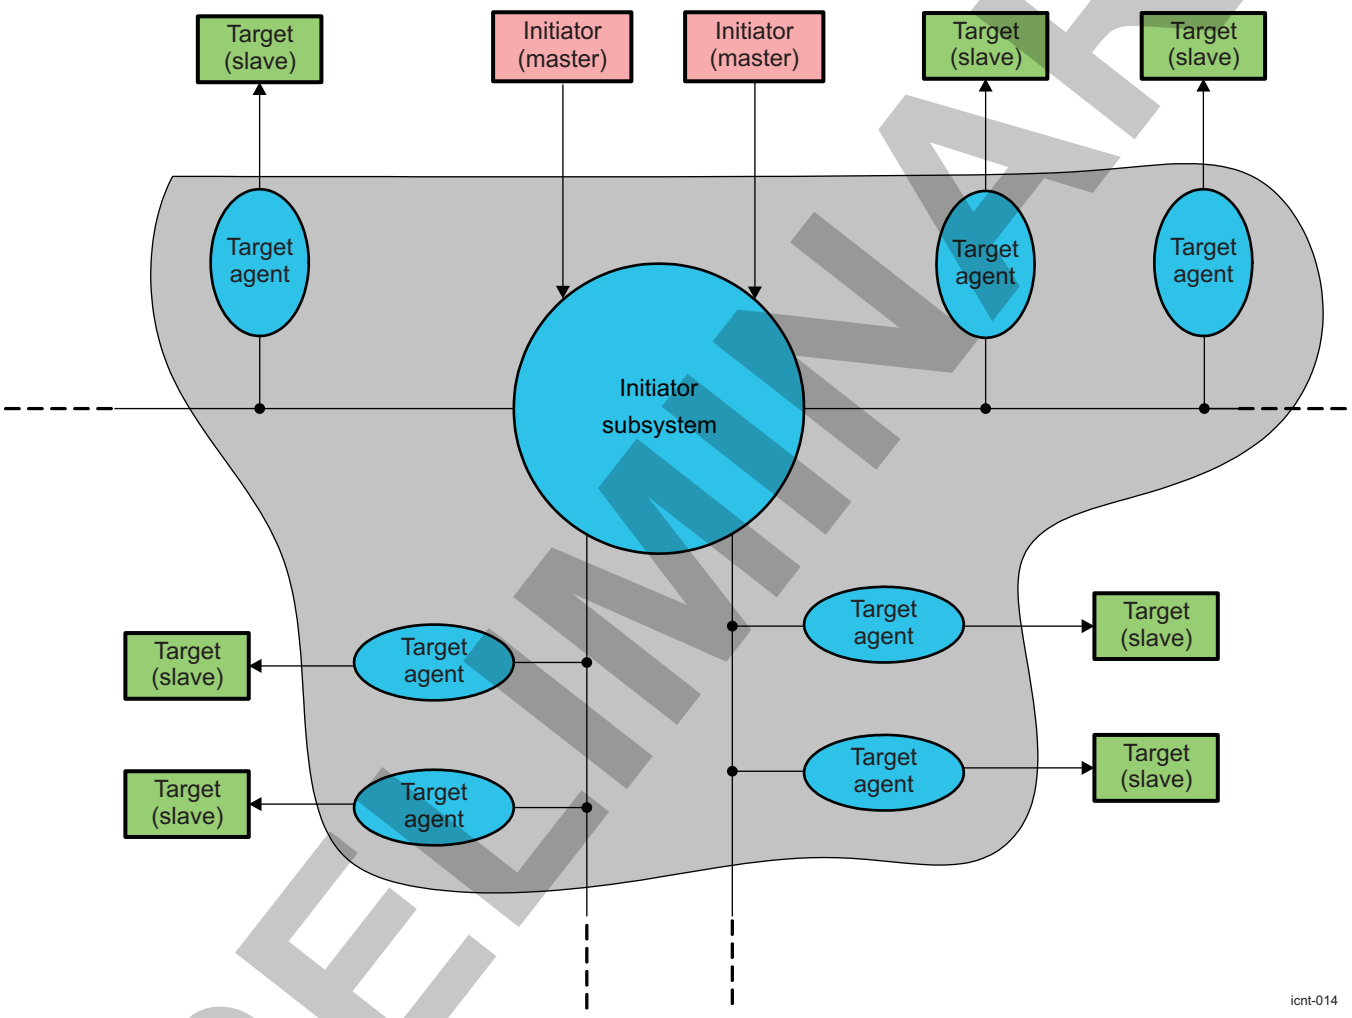
14.3.3.3 L4 Firewalls

Figure 14-10 is an internal view of the L4 interconnects in the overall interconnect. This architecture, with one initiator subsystem centralizing all initiator master requests and distributing them to all target modules (peripherals), enables the L4 interconnect firewall functions to be centralized at the L4 initiator subsystem level. The L4 firewall filters the accesses based on the configurable protection groups defined in the L4 address protection (AP) registers. Each module or TA is assigned to a protection group. The configuration is also defined in the L4 AP and is programmable on a module-per-module basis.

Figure 14-10. L4 Initiator-Target Connectivity



NOTE: As Figure 14-10 shows, targets are attached to branches. Branches do not impact the function of the L4 interconnect but are present to simplify timing closure and reduce active power consumption.

Because of the large address spaces and the number of peripherals connected to an L4 interconnect, two parameters are used to set up access permission:

- Programmable groups for initiators:
  - Eight protection groups for the L4 interconnect
- Segments divided into regions
  - 85 regions for the L4_PER interconnect
  - 112 regions for the L4_CFG interconnect
  - 30 regions for the L4_WKUP interconnect

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Protection group members are TAs with the same protection settings. A region is programmed to allow access to a unique selectable protection group. For better protection, different regions are grouped into protection group regions and associated with a protection group member.

14.3.3.3.1 Protection Group

A protection group is defined by its initiators (or members) and MReqInfo is allowed. Two registers define these two settings:

- The 64-bit CONNID_BIT_VECTOR field L4_AP_PROT_GROUP_MEMBERS_k_L and L4_AP_PROT_GROUP_MEMBERS_k_H registers define which initiator belongs to a group. A protection group is accessible by an initiator when the bit position corresponding to its ConnID is set to 1 in the CONNID_BIT_VECTOR field. Table 14-376 lists all the ConnIDs available at the L4 levels.
- The ENABLE field L4_AP_PROT_GROUP_ROLES_k_L register lists all possible MReqInfo combinations associated with the L4_AP_PROT_GROUP_MEMBERS register. Setting a Req bit in this register determines the initiators type of access. For more information, see Section 14.2.3.8, *L3 Firewall Functionality*. Two MReqInfos are used in L4 interconnects: MReqDebug and MReqSupervisor.

NOTE: Permissions are identical for read and write accesses in L4 interconnect.

k indicates the protection group number.

L indicates the region number.

Table 14-376. L4 ConnID Definition

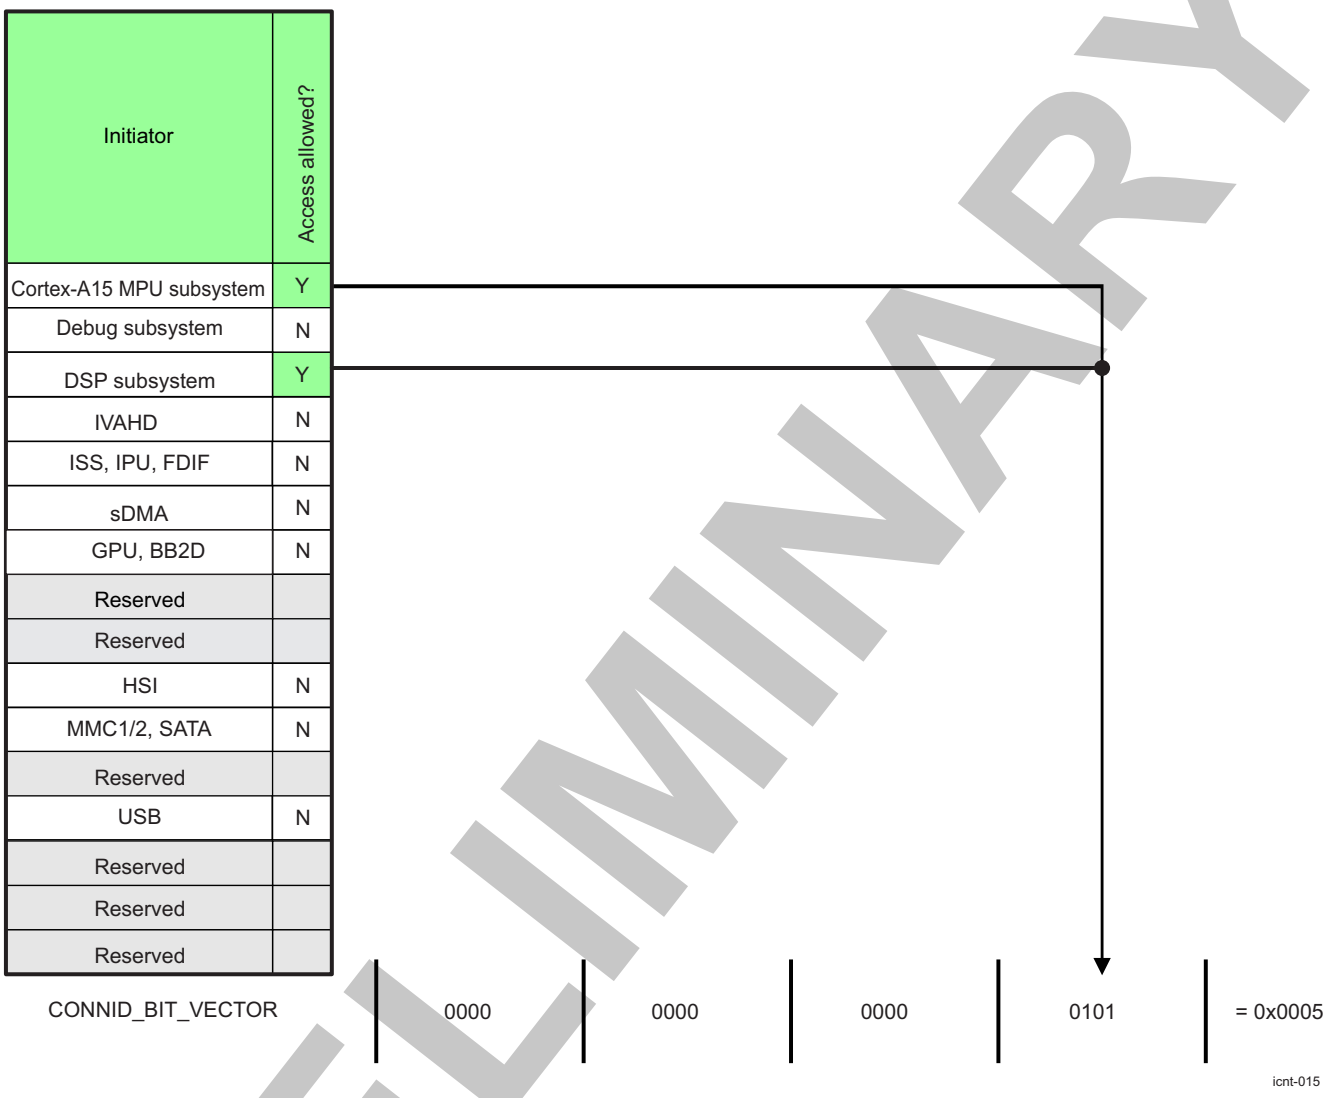
Figure 14-11 is an example of CONNID_BIT_VECTOR.

Figure 14-11. Example of CONNID_BIT_VECTOR L4_AP_PROT_GROUP_MEMBERS_k



Setting bits 0 and 2 in the PROT_GROUP_ID_1 register defines a group initiator that can access targets in protection group 1, and includes the following:

- Cortex-A15 MPU subsystem
- DSP subsystem

Protection group 1 can be applied to multiple protection regions with no limitation. Each protection region that is configured with protection group 1 enables permission access only to the two initiators.

The L4_AP_REGION_i_H PROT_GROUP_ID field determines the region to which the protection group member is attached.

The values of some CONNID_BIT_VECTOR and ENABLE fields are exported by the system control module (SCM) at reset or are user writable (see Figure 14-11 for more information).

Table 14-377 and Table 14-378 list the default configuration of the various groups for each L4 interconnect. For each group, some modules or regions are associated with it using default initiator members.

14.3.3.3.2 Segments and Regions

The protection mechanism for L4 interconnects is based on a hierarchical segmentation, as shown in Figure 14-12. By default, some regions are attached to specific protection group members. This specificity lets users set up the permission access to certain types of modules requiring the same access protection without managing region allocation.

PRELIMINARY

14.3.3.3.3 L4 Firewall Address and Protection Register Settings

Table 14-383 lists the settings of the AP registers relative to an L4 interconnect firewall. These values are computed based on the physical implementation of each L4 interconnect.

Table 14-383. L4 Firewall Register Description Overview

Register Type	Register Name	Bits	Field	Description
Segment	L4_AP_SEGMENT_i_L (1)	31:0	BASE	Segment base address
	L4_AP_SEGMENT_i_H (1)	5:0	SIZE	Segment size equals to 2^{SIZE}
Protection groups	L4_AP_PROT_GROUP_MEMBERS_k_L (2)	15:0	CONNID_BIT_VECTOR	For L4ConnID, see Table 14-376.
	L4_AP_PROT_GROUP_ROLES_k_L (2) L4_AP_PROT_GROUP_ROLES_k_H	31:0	ENABLE	See Section 14.2.3.8.3 for REQ_INFO description. (3)
Region setting	L4_AP_REGION_l_L (4)	20:0	BASE	Defines the base address of region with respect to its segment base address
	L4_AP_REGION_l_H (4)	31:28	MADDRSPACE	Target interconnect MAddrSpace
		26:24	SEGMENT_ID	Segment ID number of the region
		22:20	PROT_GROUP_ID	Protection group member attached to the region
		18:17	BYTE_DATA_WIDTH_EXP	Determines the number of bytes in an access
		14:8	PHY_TARGET_ID	Physical target ID
		6:1	SIZE	Size of the region equals to 2^{SIZE}
		0	ENABLE	Enables the region protection

(1) i = 0 to 1 for PER_AP
i = 0 to 6 for CFG_AP
i = 0 to 1 for WKUP_AP

(2) k = 0 to 7 for PER_AP
k = 0 to 7 for CFG_AP
k = 0 to 7 for WKUP_AP

(3) For L interconnects, only MReqDebug and MReqSupervisor are available.

(4) l = 0 to 84 for PER_AP
l = 0 to 111 for CFG_AP
l = 0 to 29 for WKUP_AP

14.3.3.4 L4 Error Detection and Reporting

14.3.3.4.1 IA and TA Error Detection and Logging

The L4 interconnect provides mechanisms for handling internally detected errors or errors reported by modules attached to the L4 target ports.

NOTE: L4_IA denotes the IA for all L4 interconnects: L4_PER, L4_CFG, and L4_WKUP.

L4_TA denotes the TA for all L4 interconnects: L4_PER, L4_CFG, and L4_WKUP.

The L4 interconnects handle four types of errors:

- No target core found or address hole, detected and logged at IA
- Unsupported command, detected and logged at IA
- Protection violation, detected and logged at IA (see Section 14.3.3.3, *L4 Firewalls*)
- Target does not service a request before a time-out expires. The error is detected and logged at TA (see Section 14.3.3.4.2, *Time-Out*).

Table 14-384 lists the value of the L4_IA_ERROR_LOG_L[25:24] CODE bit field stored when an error occurs.

Table 14-384. L4 CODE Bit Field Definition

CODE (bits 1:0)	Error Type	REQ_INFO	Secondary	ConnID	CMD
0	No error				
1	Unsupported command	x	x	x	x
2	Address hole	x	x	x	x
3	Protection violation	x		x	x

- No target core found/address hole: This error indicates that a request was addressed to a hole in the L4 address map. When this error occurs, an in-band error response is returned to the L3 level. The error is also logged into the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. Additionally, an address hole error code is logged to the L4_IA_ERROR_LOG_L[25:24] CODE bit field.
- Unsupported command: This error indicates that the command type of the request is not supported by the accessed target register. The error is logged into the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. An unsupported command error code is written to the L4_IA_ERROR_LOG_L[25:24] CODE bit field for the initiator interface.
- Protection violation: This error indicates that a request is not issued from an allowed initiator member or is issued with the inappropriate ReqInfo qualifiers associated with the target region. This error is reported using an in-band error and is written to the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. A protection violation error code is saved into the L4_IA_ERROR_LOG_L[25:24] CODE bit field for the same initiator interface. A protection violation is also logged in the L4_IA_AGENT_STATUS_L[31] PROT_ERROR_SECONDARY or [30] PROT_ERROR_PRIMARY bit when in debug or applicative mode, respectively.

  The L4_IA_ERROR_LOG_L[30] SECONDARY bit indicates whether the error occurred in application or debug.

  The L4_IA_ERROR_LOG_H[15:0] REQ_INFO bit field returns the type of access (REQ_INFO qualifier) that caused the error.

  The L4_IA_ERROR_LOG_L[13:8] CONNID bit field returns the ID of the initiator that caused the error.

  The L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR register logs the address for error conditions.

14.3.3.4.2 Time-Out

A time-out mechanism can be enabled at the interconnect level and on a per-target basis. If the mechanism is enabled for a TA and interconnect and commands are not accepted or responses are not returned within the expected delay, the L4 interconnect generates an error event.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

NOTE: The time-out mechanism is not available on the L4_WKUP interconnect, but L4_WKUP time-outs are detected in CFG_TA_L4WKUP of the L4_CFG interconnect.

The error is logged in the L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT bit. The affected TA enters an error state that causes it to send an error response to any new request targeted at it. To recover from this state, system software must reset the TA. The time-out is counted starting from the moment a command is presented to the target, regardless of the target response to this command.

The L4 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected TAs. The time-base circuit offers four possible sets of four time-base signals. The time-base signals are selected by programming the L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE bit field.

The selected time-base signals are available at any TA. Each TA can be programmed to refer to one of these four time-base signals, using the L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT bit field. These four signals are referred to as 1X time-base, 4X time-base, 16X time-base, and 64X time-base.

Table 14-385 lists all values in number of L4 clock cycles.

Table 14-385. L4 Time-out Link and TA Programming

	L4_TA_AGENT_CONTROL_L [2:0] REQ_TIMEOUT				
L4_LA_NETWORK_CONTROL_L[2:0] TIMEOUT_BASE	**0**	**1**	**2**	**3**	**4**
0	All L4 time-out features are disabled.				
1	Locally disabled	64	256	1024	4096
2		256	1024	4096	16,384
3		1024	4096	16,384	65,536
4		4096	16,384	65,536	262,144

The default reset value is 0x2 for REQ_TIMEOUT and 0x4 for TIMEOUT_BASE, implying 16,384 clock cycles.

A time-out condition is detected when the command acceptance or the response is not received after a delay of from one to three time-base periods.

Example:

- L4 frequency = 65-MHz, 15.3-µs period
- TIMEOUT_BASE = 4 in the L4_LA_NETWORK_CONTROL_L register
- REQ_TIMEOUT = 2 in the L4_TA_AGENT_CONTROL_L for TA A
- REQ_TIMEOUT = 4 in the L4_TA_AGENT_CONTROL_L for TA B

At agent A, the time-base unit is 16,384 cycles. A time-out is issued when a request to the attached module is not accepted, or no response is sent after a delay of 252 µs to 756 µs.

At agent B, the time-base unit is 262,144 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 4 ms to 12 ms.

When a time-out condition is detected, the TA logs the error in the L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT bit, and it also reports the error to the IA, which forwards it to the L3 interconnects.

After the time-out is detected and logged, the behavior of the attached module is ignored. A new request targeting the module arriving at the timed-out TA receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, software is assumed to first reset the faulty module and then the TA using the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit.

14.3.3.4.3 Error Reporting

Figure 14-13 shows the error-reporting scheme used in the L4 interconnects. All L4 in-band errors are reported to their respective L3 TA, where errors are converted in an out-of band error signal (the L3 applicative and debug composite flags) going to the L3 INTCs.

Two levels of mask are present to report the error at INTC level:

- At the applicative and debug composite flag, to enable interrupt reporting, the following bits must be set:
  - L4_CFG in L3_CLK1_FLAG_MASK_0[3] and L3_CLK1_FLAG_STATUS_1[3]
  - L4_PER in L3_CLK2_FLAG_MASK_0[17][16][15][6] and L3_CLK2_FLAG_STATUS_1[17][16][15][6]
- At the L3 TA level, see Section 14.2.1, *L3 Interconnect*.

Figure 14-13. L4 Error Reporting

14.3.3.4.4 Error Recovery

Setting the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit to 1 initiates the software reset period. Software reset must be asserted for at least 16 cycles of the target module interface clock, which can be a divided clock with respect to the L4 clock.

During the software reset period:

- Requests sent to the target module receive error responses. Therefore, if the faulty request is part of a DMA transfer, it is necessary to stop the DMA to prevent unwanted errors.
- Requests sent to the TA register block are processed as usual.
- The L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT status bit is cleared.

Setting the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit to 0 terminates the software reset period.

Reset the attached module to complete the recovery.

14.3.3.4.5 Firewall Error Logging in the Control Module

When a protection violation occurs, an interrupt is send to the INTCs (if enabled). An in-band error is sent back to L3 IA and an out-of-band error can also be logged in the CONTROL.CONTROL_SEC_ERR_STATUS register in the SCM. These out-of-band errors are enabled and disabled at the L4 IA level by setting the L4_IA_AGENT_CONTROL_L[31][30] PROT_ERROR_SECONDARY_REP or PROT_ERROR_PRIMARY_REP bit to 1 for debug and application mode, respectively.

At the control module level, two logging registers are used, depending on the mode:

- In application mode or primary error reporting:
  - CONTROL_CORE_SEC_ERR_STATUS_FUNC[16] = L4_CFG protection violation
  - CONTROL_CORE_SEC_ERR_STATUS_FUNC[17] = L4_PER protection violation
  - CONTROL_CORE_SEC_ERR_STATUS_FUNC[22] = L4_WKUP protection violation
- In debug mode or secondary error reporting:
  - CONTROL_CORE_SEC_ERR_STATUS_DEBUG[16] = L4_CFG protection violation
  - CONTROL_CORE_SEC_ERR_STATUS_DEBUG[17] = L4_PER protection violation
  - CONTROL_CORE_SEC_ERR_STATUS_DEBUG[22] = L4_WKUP protection violation

NOTE: The CONTROL_CORE_SEC_ERR_STATUS_xxx registers are only readable.

Figure 14-14 shows the global protection error reporting to the control module.

14.3.4 L4 Interconnect Programming Guide

14.3.4.1 L4 Interconnect Low-level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L4 interconnect module.

14.3.4.1.1 Global Initialization

14.3.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the L4 interconnect module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the L4 interconnect. For more information, see Section 14.3.2, *L4 Interconnect Integration*.

Table 14-386 lists the surrounding modules.

Table 14-386. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	For more information about the configuration of the module, see Section 3.1.1, *Power, Reset, and Clock Management*.
Control module	For more information about the configuration of the module, see Figure 18-1, *Control Module*.
MPU INTC	Configure the MPU INTC to enable the interrupts from L4 interconnect module. SeeSection 17.1 *Interrupt Controllers*.
sDMA	For more information about the configuration of the sDMA, see Section 16.1, *sDMA*.
L3 interconnect	For more information about the interconnect configuration, see Section 14.2.1, *L3 Interconnect*.

14.3.4.1.2 Operational Modes Configuration

14.3.4.1.2.1 L4 Interconnect Error Analysis Mode

14.3.4.1.2.1.1 Main Sequence: L4 Interconnect Error Analysis Mode

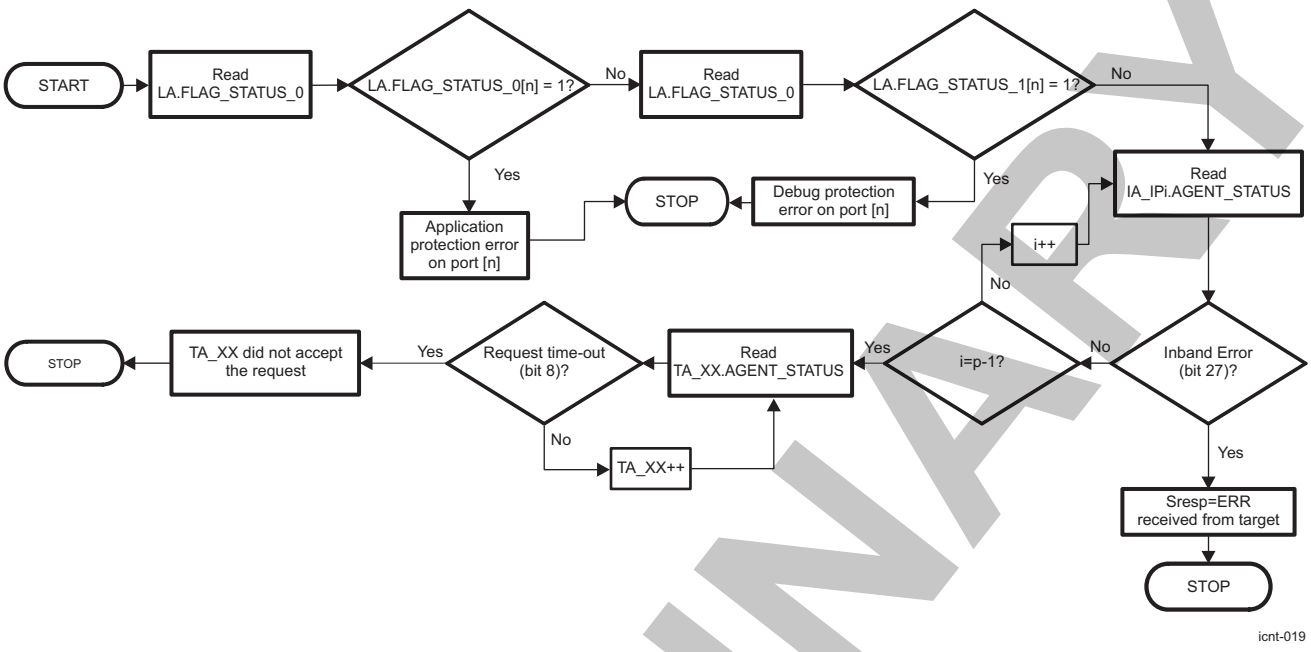
The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

Figure 14-15 shows the software sequence required in most cases.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 14-15. Typical Error Analysis Sequence



NOTE: L4 interconnects don't log any address or other specific information for a custom error returned from any target IP. They rather pass an error response ut to the master supposed to analyze it.

In case of posted writes, the master access completes before it actually completed at the end slave level, this way no error response is sent back to the master, making it impossible to have a direct way of uderstanding the origin of L4 error during posted writes. However, even though no address is logged, an error flag is generated and needs to be processed.

14.3.4.1.2.1.2 Subsequence: L4 Interconnect Protection Violation Error Identification

This procedure describes the protection violation error identification (see Table 14-387).

Table 14-387. Protection Violation Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	
Read initiator ID.	L4_IA_ERROR_LOG_L[11:8] CONNID	
Read command that cause the error.	L4_IA_ERROR_LOG_L[2:0] CMD	
Read address of request that caused the error.	L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR	
IF: Is it a primary error?	L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY	=0x1
Read status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[17:16]	
Write 1 to clear status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[17:16]	0x3
Write 1 to clear IA status bit.	L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY	0x1
ELSE		
Read status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[17:16]	
Write 1 to clear status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[17:16]	0x3

31:25	RESERVED	Read returns 0.	R	0x00
24	SERROR_REP	Enable logging of error	R	0x0
23:11	RESERVED	Read returns 0.	UNDEFINED_TYPE_STRING	

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
10:8	REQ_TIMEOUT	Time-out Bound. Values are: 0 - No time-out 1 - 1x base cycles. 2 - 4x base cycles. 3 - 16x base cycles. 4 - 64x base cycles.	RW	0x2
7:1	RESERVED	Read returns 0.	R	0x00
0	OCP_RESET	The OCP_RESET field controls the OCP reset signal to the attached core. Setting this bit clears any pending transfers and resets the OCP interface. The bit must be cleared to deassert the OCP reset signal. When the software reset feature is available on a target agent, the target agent OCP must also have a reset signal directed to the target core.	RW	0

RESERVED							CLOCK_GATE_DISABLE	RESERVED			THREAD0_PRI	RESERVED											EXT_CLOCK	RESERVED							

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Read returns 0.	R	0x00
24	CLOCK_GATE_DISABLE	When set to 1 this field disables all clock gating.	RW	0
23:21	RESERVED	Read returns 0.	R	0x0
20	THREAD0_PRI	Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads.	R	1
19:9	RESERVED	Read returns 0.	R	0x000
8	EXT_CLOCK	When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off.	R	1
7:0	RESERVED	Read returns 0.	R	0x00

Memory Subsystem

This chapter introduces the memory subsystem of the device.

NOTE: Some of the memory subsystem features, primarily those concerning the device I/O pads, are not available in all OMAP54xx devices.

For details, see , *OMAP543x Family and Device Identification*, in Chapter 1, *Introduction*, and the corresponding TRM appendix and device data manual.

Topic **Page**

15.1 Memory Subsystem Overview 3343
15.2 Dynamic Memory Manager 3348
15.3 EMIF Controller 3437
15.4 General-Purpose Memory Controller 3551
15.5 Error Location Module 3691
15.6 On-Chip Memory (OCM) Subsystem 3718

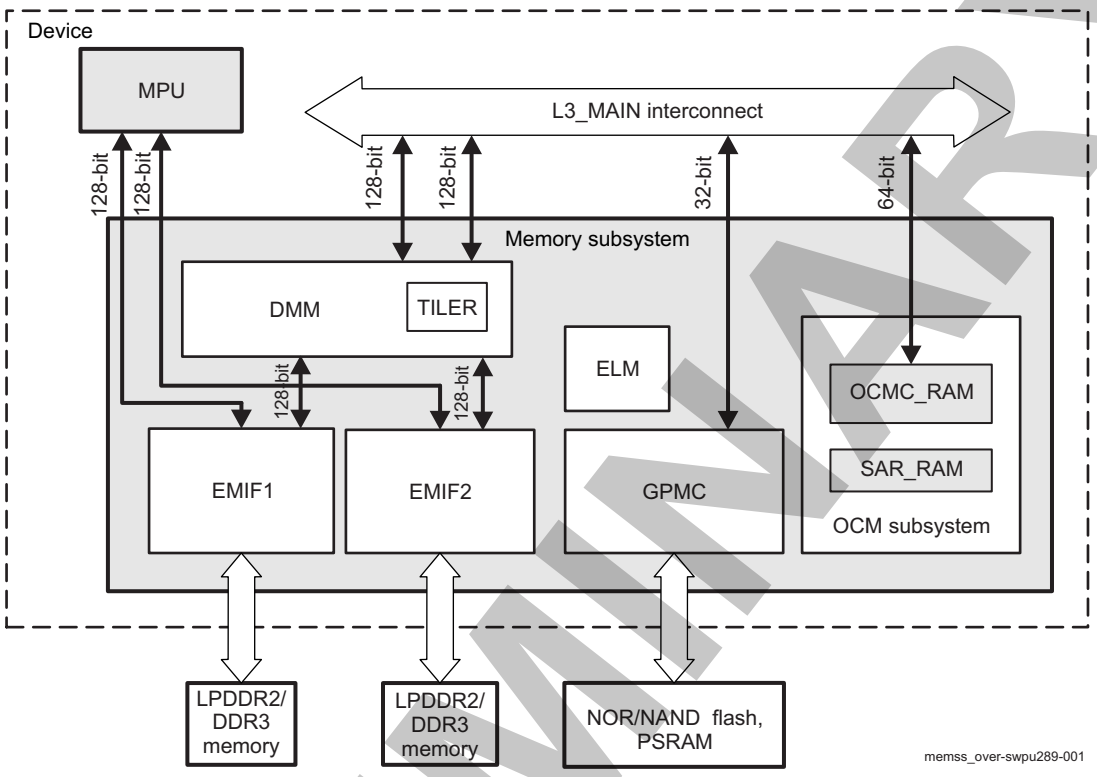
15.1 Memory Subsystem Overview

Figure 15-1 shows a functional diagram of all memory subsystems in the device.

Figure 15-1. Memory Subsystem Functional Diagram



15.1.1 DMM Overview

The dynamic memory manager (DMM) module is typically located immediately in front of the synchronous dynamic random access memory (SDRAM) controllers (EMIF), as shown in Figure 15-1, *Memory Subsystem Functional Diagram*.

In a broad sense, the DMM manages various aspects of memory accesses such as:

- Initiator-indexed priority generation
- Multizone SDRAM interleaving configuration
- Block object transfer optimization – tiling
- Centralized low-latency page translation – MMU-like feature

The dynamic qualifier for memory management highlights the software configurability, and hence the runtime nature, of the four aspects of memory management handled by the DMM.

15.1.1.1 DMM Features

From a functional perspective, the role of the DMM is to:

- Add initiator-based priority to any incoming requests
- Perform to/from tiling conversions of tiled requests
- Make on-the-fly basic transforms, such as quadrant rotations and mirroring
- Optionally, provide a low-latency page-based translation to handle memory fragmentation – MMU
- Distribute the traffic on all attached memory controllers according to the interleaving configuration

The main features of the DMM are:

- Programmable multizone DRAM mapping and interleaving configuration

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- Programmable initiator-based request priority extension
- Multichannel memory transfer optimization
- Single SDRAM page request generation
- Low-latency interconnect port
- Page-grained address translation to manage memory fragmentation
- Automatic synchronized reloading of the address translation table

15.1.2 TILER Overview

The tiling and isometric lightweight engine for rotation (TILER) is a submodule of the DMM (see Figure 15-1) and is therefore described in Section 15.2.1, *Dynamic Memory Manager*.

The TILER is intended to improve bidimensional (tiled) block transfer efficiency. It is, therefore, a module aimed at:

- Primarily, efficient handling of 2-dimension (2D) data mapped in tiles, such as video or graphics macroblocks
- Optionally, managing the memory fragmentation and zero-copy physical frame-buffer swapping through a page-grained translation
- Making isometric (distance preserving) transforms, such as 90-, 180-, or 270-degree rotations, with a horizontal or vertical reflection

The lightweight qualifier of this engine highlights its limited support of isometric transforms, as:

- Rotation performs only basic quadrant rotations by some multiple of 90 degrees.
- Reflection is limited to horizontal and vertical flip.
- Translation is restricted to a 4-KiB page granularity.

Written differently, the functionality of the TILER is to map a 2D virtually addressed interconnect request into one or more physically addressed interconnect requests by:

- Transforming the virtual address, data, and byte-enable to match the requested 0-, 90-, 180-, or 270-degree orientation in a tiled 2D addressing space
- Optionally, translating the oriented tiled address by a page-specific vector to manage memory fragmentation and physical object aliasing

15.1.2.1 TILER Features

The main features of the TILER are:

- Efficiency improvement of 2D block access on SDRAMs
- Optimized interlaced access on tiled frames
- 2D virtual-to-physical address translation of SDRAM bidimensional objects to handle rotation
- Page-grained address translation to manage memory fragmentation and physical buffer aliasing
- Unlimited number of 2D tiled objects supported in any (0, 90, 180, or 270 degrees) orientation
- Full bandwidth use by minimizing the size of raster-based initiator buffers
- Optimization of multichannel memory transfers
- Interconnect request granularity balance (in X and Y directions)

15.1.3 EMIF Overview

The two external memory interface (EMIF) modules are typically located near the DMM module, as shown in Figure 15-1 , *Memory Subsystem Functional Diagram*.

The EMIF module provides connectivity between the device and LPDDR2-type or DDR3-type of memories and manages data bus read/write accesses between external memories and device subsystems having master access to the L3_MAIN interconnect and DMA capability.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

15.1.3.1 Main Features

Each EMIF module has the following capabilities:

- Supports JEDEC standard-compliant DDR3-SDRAM, DDR3L-SDRAM, and LPDDR2-SDRAM (S2 and S4) devices
- 4-GiB SDRAM address range over two chip-selects (2 GiB per chip-select) (configurable with the dynamic memory manager (DMM) module; see Section 15.2.1, *Dynamic Memory Manager*, for more information)

NOTE: Even though the two EMIF modules work independently and can have connected different (LPDDR2 and DDR3) memories at a time, the device package restricts the physical connections to only one memory type (LPDDR2 or DDR3) per device. See more details about device family in , *Introduction*

- Supports SDRAM devices with one, two, four, or eight internal banks
- Data bus widths:
  - 128-bit L3_MAIN (system) interconnect data bus width
  - 128-bit port for direct connection with MPU subsystem
  - 32-bit SDRAM data bus width
- Supports CAS latencies:
  - DDR3: 5, 6, 7, 8, 9, 10, and 11
  - LPDDR2: 3, 4, 5, 6, 7, and 8
- Supports 256-, 512-, 1024-, and 2048-word page sizes
- Supported burst length: 8
- Supports sequential burst type
  - For LPDDR2, burst read can be interrupted by another read, burst write can be interrupted by another write.
  - DDR3 does not support the burst interrupt of a BL8 command
- SDRAM auto initialization from reset or configuration change for DDR3 (LPDDR2 needs to have initalization started via software)
- Supports bank interleaving across both chip-selects
- Supports self refresh and power-down modes for low power
- Supports deep power-down mode for LPDDR2 for low power
- Partial array self-refresh and temperature-controlled self-refresh modes for low power. Temperature-controlled self-refresh is supported only for mobile SDRAM having on-chip temperature sensor.
- Supports temperature monitoring for LPDDR2
- Output impedance (ZQ) calibration
- Supports on-die termination (ODT) on DDR3
- Supports prioritized refresh
- Programmable SDRAM refresh rate and backlog counter
- Programmable SDRAM timing parameters
- Write/read leveling/calibration and data eye training for DDR3.

The EMIF modules do not support:

- Burst chop for DDR3.
- Auto precharge
- Per-bank refreshes for LPDDR2-SDRAM

15.1.4 GPMC Overview

The general-purpose memory controller (GPMC) is an unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in nonmuxed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

15.1.4.1 GPMC Features

The GPMC is the external memory controller of the device. The GPMC data access engine provides a flexible programming model for communication with all standard memories. The GPMC supports various accesses:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, and 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8, and 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8, and 16 Word16)
- Address/data-multiplexed access
- Little- and big-endian access

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (nonburst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit nonmultiplexed device with limited address range (2 KiB)
- External 16-bit address/data-multiplexed NOR flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo-SRAM (pSRAM) device

The main features of the GPMC are:

- 8- or 16-bit-wide data path to external memory device
- Supports up to eight CS regions of programmable size and programmable base addresses in a total address space of 512 MiB
- Supports transactions controlled by a firewall
- On-the-fly error code detection using the Bose-ChaudhurI-Hocquenghem (BCH) (t = 4, 8, or 16) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- Fully pipelined operation for optimal memory bandwidth use
- External device clock provided from L3_MAIN clock (GPMC_FCLK) divided by 1, 2, 3, or 4
- Supports programmable autoclock gating when no access is detected
- Independent and programmable control signal timing parameters for setup and hold time on a per-chip basis. Parameters are set according to the memory device timing parameters, with a timing granularity of one GPMC_FCLK clock cycle.
- Flexible internal access time control (WAIT state) and flexible handshake mode using external WAIT pin monitoring
- Support bus keeping
- Support bus turnaround
- Prefetch and write posting engine associated with system DMA (sDMA) to achieve full performance from the AND device with minimum effect on NOR/SRAM concurrent access

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: Page mode is available only in nonmultiplexed mode.

15.1.5 ELM Overview

In the case of NAND modules with no internal correction capability, sometimes referred to as bare NAND, the correction process can be delegated to the error location module (ELM) used in conjunction with the GPMC.

15.1.5.1 ELM Features

The ELM features:

- 4, 8, and 16 bits per 512-byte block error location based on BCH algorithm
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation when error location process completes:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

15.1.6 OCM Overview

The on-chip memory (OCM) subsystem consists of the following OCM controllers.

- One connected to an on-chip RAM (SAR RAM)
- One connected to an on-chip SRAM (L3 SRAM)

Each memory controller has its own dedicated interface to the L3_MAIN interconnect.

15.2 Dynamic Memory Manager

15.2.1 DMM Overview

This section describes the dynamic memory manager (DMM) and its tiling and isometric lightweight engine for rotation (TILER) submodule.

The DMM is introduced in Section 15.1, *Memory Subsytem Overview*.

The function of the DMM is to:

- Add initiator-based priority to any incoming requests
- Perform to-and-from tiling conversions of tiled requests
- Make on-the-fly basic transforms, such as quadrant rotations and mirroring
- Optionally provide a low-latency page-based translation to handle memory fragmentation – memory management unit (MMU)
- Distribute the traffic on all attached memory controllers according to the interleaving configuration

The TILER is also introduced in Section 15.1, *Memory Subsystem Overview*.

The functions of the TILER are:

- Primary handling efficiently 2-dimensional (2D) data mapped in tiles, such as video or graphics macroblocks
- Optionally managing the memory fragmentation and zero-copy physical frame buffers swapping through a page-grained translation
- Allowing optimized interlaced accesses on tiled frames
- Making (distance preserving) transforms, such as 90-, 180-, or 270-degree rotations, with a horizontal or vertical reflection
- Interleaving the memory accesses among the two memory controllers (also called EMIF). For more information, see Section 15.3.1, *EMIF Controller*.

Figure 15-2 is an overview of the DMM and TILER in the device.

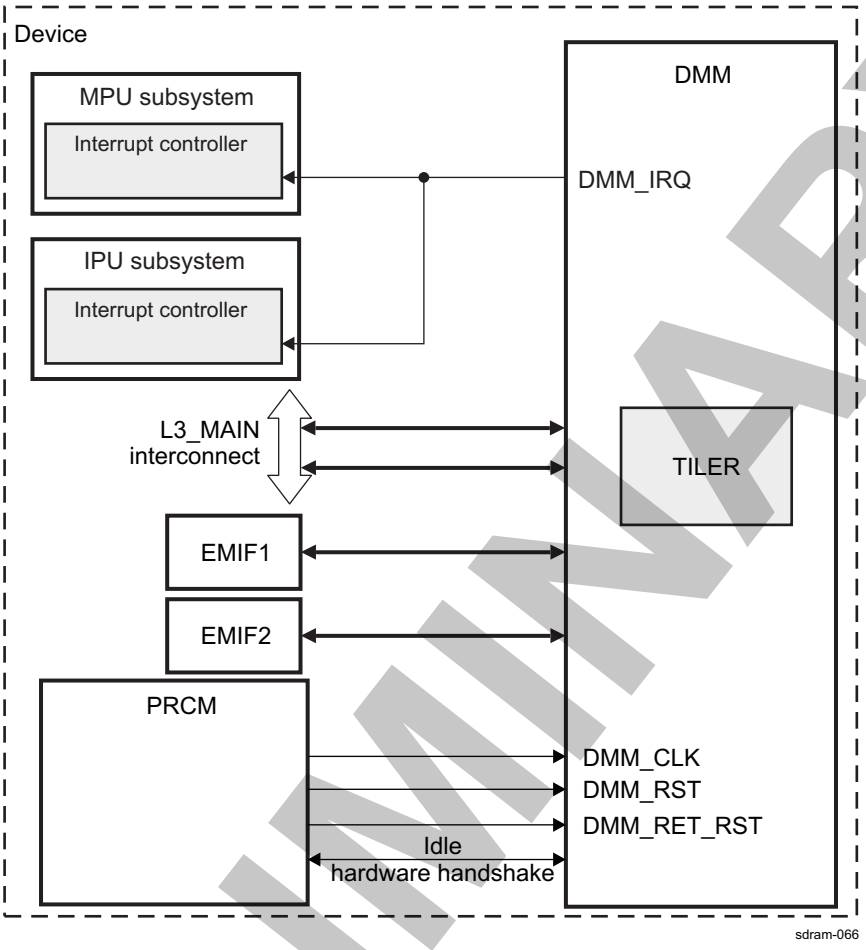
Figure 15-2. DMM and Tiler Overview



15.2.2 DMM Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- IDLE hardware handshake (the DMM supports only smart-idle mode)
- No STANDBY hardware handshake
- No wake-up request
- No system direct memory access (sDMA) requests
- One interrupt line for interrupt request (IRQ)
- One functional clock

Figure 15-3 shows the integration of DMM in the device.

15.2.3 DMM Functional Description

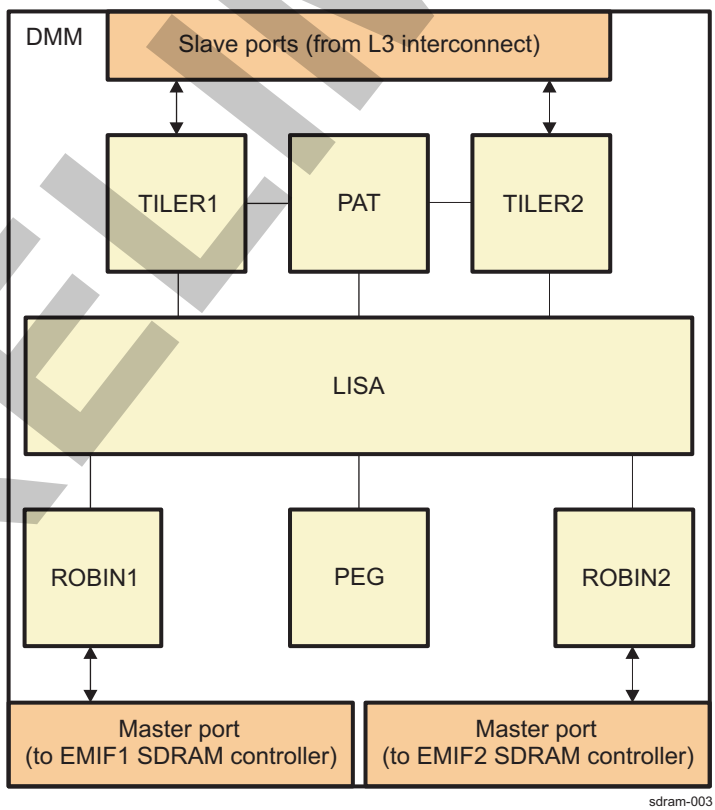
15.2.3.1 DMM Block Diagram

Figure 15-4 shows the DMM macro architecture. The DMM consists of six blocks:

- Two TILERs, each with its own interconnect slave port for converting requests back and forth between the input virtual addressing mode and the output physical tiledaddressing mode. The tiling conversions of requests, write data, and responses is performed entirely in the TILER blocks.
- Two reordering buffer and initiator nodes (ROBINs), each with its own interconnect master port to initiate requests to the SDRC and allow tiled data, tiled response, and split response reconstruction. The ROBIN block manages only the reordering buffer and performs data reordering due to the orientation.
- A physical address translator (PAT) for managing the memory fragmentation
- A priority extension generator (PEG) to generate priorities required by the SDRC; these priorities are not used in the DMM.
- A local interconnect and synchronization agent (LISA) to synchronize all DMM subsystems and provide access to their configuration registers

Figure 15-4 is a block diagram of the DMM.

Figure 15-4. DMM Block Diagram



PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

CAUTION

The interconnect must ensure that virtually addressed requests target only a TILER port.

15.2.3.2 DMM Clock Configuration

Table 15-5 describes the DMM clocks.

Table 15-5. DMM Clocks

Signal	I/O[1]	Description
DMM_CLK	I	Functional and interface clock

(1) I = Input; O = Output

The DMM is concerned with SDRC management and is in the MEMIF clock domain among the SDRCs. The DMM is a fully synchronous module, which uses the clock and clock-enable signals provided in the MEMIF clock domain to generate its interface and functional clocks.

To configure DMM_CLK control and settings, see Table 15-2.

15.2.3.3 DMM Power Management

DMM power is supplied by the CORE power domain, and DMM power management complies with system power-management guidelines.

Table 15-6 describes the power-management features available for the DMM module.

Table 15-6. DMM Local Power-Management Features

Feature	Registers	Description
Slave idle modes	DMM_SYSCONFIG[3:2] SIDLEMODE bit field	Only smart-idle wake-up mode is available.

15.2.3.4 DMM Interrupt Requests

Errors in PAT area refill registers are reported through the DMM_PAT_STATUS_i[15:10] ERROR bit field (see Table 15-7).

Table 15-7. DMM Hardware Status Features

Feature	Type	Register	Description
PAT error flags	Read-only	DMM_PAT_STATUS_i[15:10] ERROR (where i = 0 to 3)	Unexpected update of the PAT area refill registers

Table 15-8 lists the event flags, and their masks, that can cause module interrupts.

Table 15-8. Events

Interrupt	Event Flag	Event Mask
ERR_LUT_MISS3	DMM_PAT_IRQSTATUS[31] ERR_LUT_MISS3 DMM_PAT_IRQSTATUS_RAW[31] ERR_LUT_MISS3	DMM_PAT_IRQENABLE_SET[31] ERR_LUT_MISS3 DMM_PAT_IRQENABLE_CLR[31] ERR_LUT_MISS3
ERR_UPD_DATA3	DMM_PAT_IRQSTATUS[30] ERR_UPD_DATA3 DMM_PAT_IRQSTATUS_RAW[30] ERR_UPD_DATA3	DMM_PAT_IRQENABLE_SET[30] ERR_UPD_DATA3 DMM_PAT_IRQENABLE_CLR[30] ERR_UPD_DATA3

15.2.3.5 DMM

15.2.3.5.1 DMM Concepts

The DMM introduces the concepts of dynamic mapping and DMM atomic units.

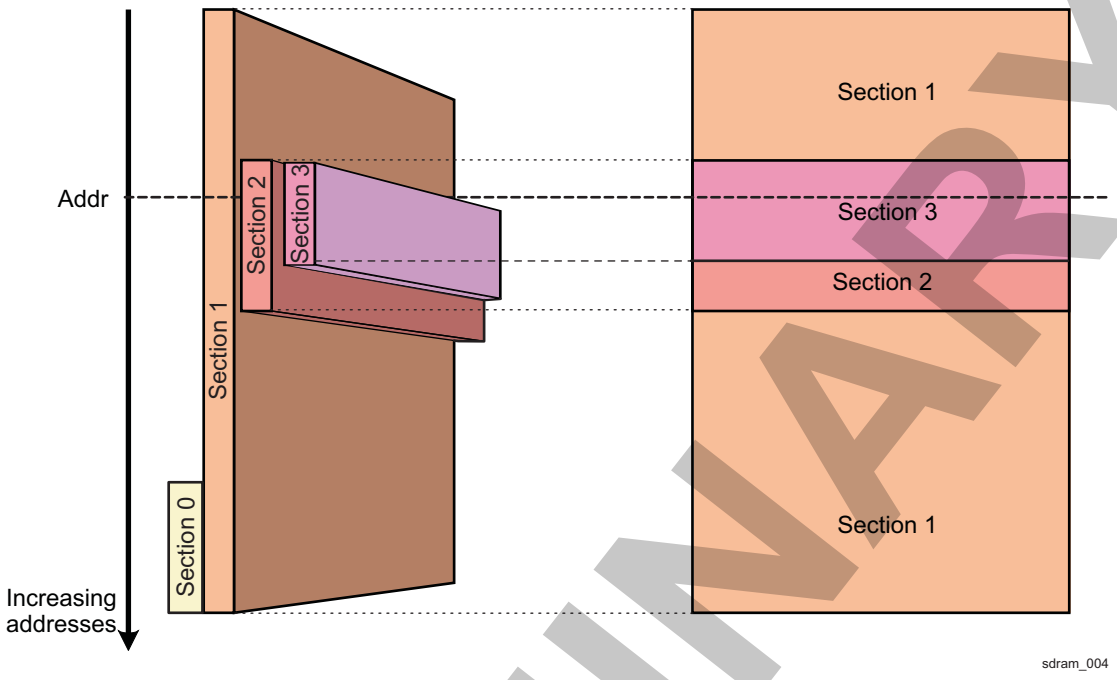
15.2.3.5.1.1 Dynamic Mapping

The DMM manages its internal memory space as an ordered set of up to four sections. Figure 15-5 shows the DMM sections and memory mapping.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 15-5. DMM Sections and Memory Mapping



In the DMM, a section is:

- A segment of 16MiB to 2GiB, which is power-of-two in size and aligned to that size in the system map
- An area with a constant interleaving scheme: constant interleaving granularity on a constant set of SDRC (EMIF) targets
- Given a priority equal to its index: the higher the index, the higher the priority

NOTE: Whenever a request hits more than one DMM section, it follows the interleaving scheme of the section having the highest index.

The interleaving configuration of the DMM, its section-based dynamic memory mapping, is shown on the right in Figure 15-5. In this example, a request at the system address Addr follows the interleaving scheme of section 3, although it hits sections 1, 2, and 3. Similarly, the DMM configuration given in this example prevents any request from using the interleaving scheme of section 0, because section 0 is fully masked by section 1, which has a higher priority.

Each of the four sections is configured through a DMM_LISA_MAP_i register, where i = 0 to 3.

NOTE: The DMM and SDRC registers (and EMIF registers; see Section 15.3.1, *EMIF Controller*) are declared in two extra static DMM sections of the highest priority so that they cannot be masked by any standard programmable DMM section.

NOTE: The DMM atomic size is:

- 1KiB in noninterleaved sections
- Equal to the interleaving granularity (128, 256, or 512 bytes) in interleaved sections

15.2.3.5.1.2 Address Mapping

The address mapping inside the DMM is configurable through up to four sections. A DMM section description fits in a single register (DMM_LISA_MAP_i). Each section is defined based on:

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

- Its system address: The base address of the decoding range for the section
- Its size: The encoding is the number of bits used in the upper 8 bits of the incoming system address
- Its physical address: The base address of the memory range access in the external memory controller
- Its address space: The address space used on the external memory controller (for the DMM) when hitting this section. For details, see , *Local Interface*.
- The target memory controller. A section may hit a single or pair of controllers.
- Its interleaving definition

The address decoding is priority-based. In case of overlapping sections, only the highest-order one is hit. Register memory spaces have priority over regular memory sections. In case of four sections, the priority order is therefore:

1. Registers
2. DMM_LISA_MAP_3
3. DMM_LISA_MAP_2
4. DMM_LISA_MAP_1
5. DMM_LISA_MAP_0

All register-related addresses are reserved and fixed in the overall address mapping:

- DMM registers: 0x4E00_0000 to 0x4FFF_FFFF
- EMIF1 registers: 0x4C00_0000 to 0x4CFF_FFFF
- EMIF2 registers: 0x4D00_0000 to 0x4DFF_FFFF

There is no overlapping between register sections.

NOTE: Section decoding happens after PAT address translation in the case of TILER. In non-bypass mode, the system address considered for TILER accesses is the virtual address computed based on the PAT translation tables.

The DMM_LISA_LOCK register is used to lock the configuration once set. If written to 1, the LOCK bit prevents further writes to all DMM_LISA_MAP_i registers. The LOCK bit cannot be written back to 0. A reset is required to reprogram the sections.

15.2.3.5.1.3 Address Translation

The PAT engine of the DMM is composed of a 32-k entry physical address translation vector table and one or two refill engines. The refill engine is a specialized DMA for refilling the content of the PAT table.

The address translation mechanism is available only when the incoming request hits a page mode or tiled mode container; that is, when the incoming address targets the TILER or its aliased view in the system addressing space. Otherwise, the PAT logic is bypassed so that the resulting physical address corresponds to the input address.

The PAT engine supports multiple address translation schemes, called views, which can be bound to one or more initiators through a view mapping mechanism.

15.2.3.5.1.3.1 PAT View Mappings

The PAT engine can have up to 16 groups of initiators that share a set of four PAT views. The connection from an initiator to a PAT view is made through the DMM_PAT_VIEW register. Given that each PAT view index is coded on 4 bits, the DMM_PAT_VIEW register is a 64-bit register split into two 32-bit registers (DMM_PAT_VIEW0 for the first eight PAT view indexes and DMM_PAT_VIEW1 for the last eight PAT view indexes.

The PAT view index that corresponds to the initiator having the value i as the 4 most-significant bits (MSBs) of its L3 ConnID uses the view referenced in entry i of the DMM_PAT_VIEW. For example, the initiator 0xC7 uses the thirteenth view index of the DMM_PAT_VIEW register, the fifth view index in the DMM_PAT_VIEW1 register.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

The PAT view index of the initiator i is found in the Vi field. The Wi field is aimed at writing the corresponding Vi. When writing to the DMM_PAT_VIEW registers, the only Vi view indexes that are updated are those having their corresponding Wi bit, and byte enable, set. The Wi bits are always read as 0. For instance, to set the PAT view indexes V3 and V7 to 2 and 1, respectively, the DMM_PAT_VIEW0 register must be written with 5000 6000h.

15.2.3.5.1.3.2 PAT View Map Base Address

The PAT view map base address defines the base address of all PAT translated addresses.

Bit [31] of all PAT translated addresses is set to BASE_ADDR. For example, if the DMM_PAT_VIEW_MAP_BASE register is set to 8000 0000h, all PAT translated addresses will have bit [31] set to 1 so that the translated addresses range from 8000 0000h to FFFF FFFFh. All reserved bits of this DMM PAT base address register are read to 0.

15.2.3.5.1.3.3 PAT Views

A PAT view defines the kind of physical address translation to perform for each mode accesses (page, 8-bit, 16-bit and 32-bit). Each mode of each PAT view can be configured to use a container-grained translation or page-mode translation.

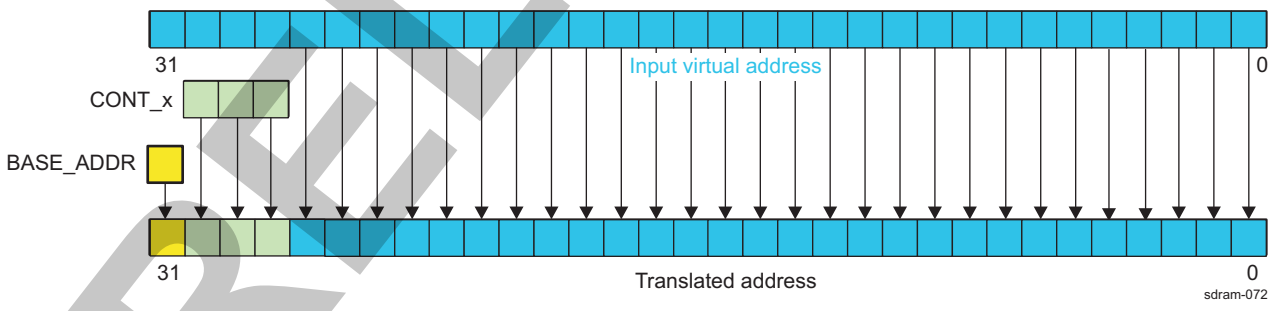
15.2.3.5.1.3.3.1 PAT Direct Access Translation

The container-grained translation is named the direct access. In this mode, the translation vector is given directly by the CONT_x bit field that corresponds to the accessed mode.

- A page mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[26:24] CONT_PAGE bit field concatenated with 1 (bit 27 of translated address).
- A 32-bit mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[18:16] CONT_32 bit field concatenated with 0 (bit 27 of translated address).
- A 16-bit mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[10:8] CONT_16 bit field concatenated with 0 (bit 27 of translated address).
- An 8-bit mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[2:0] CONT_8 bit field concatenated with 0 (bit 27 of translated address).

Figure 15-6, *PAT Direct Access Translation* describes PAT direct access translation .

Figure 15-6. PAT Direct Access Translation



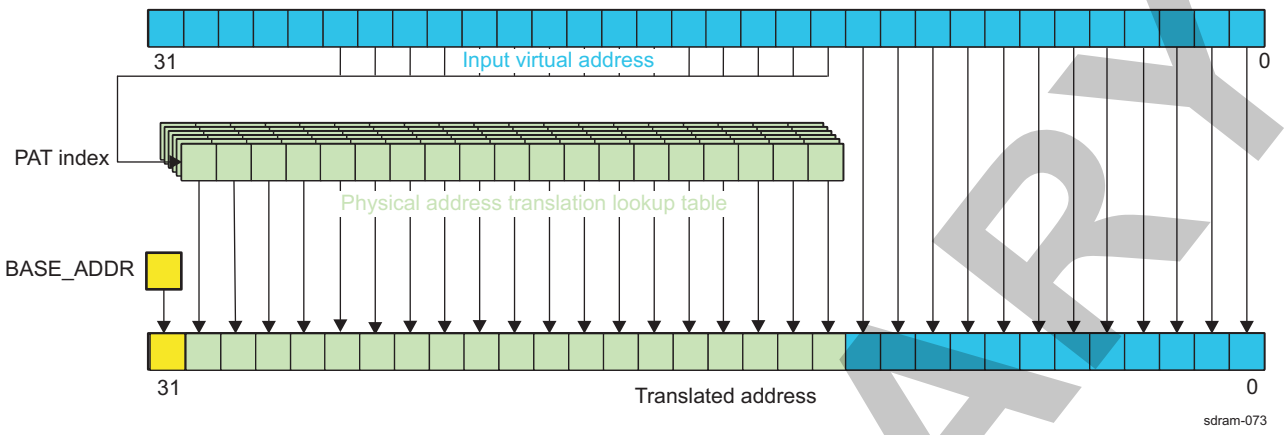
15.2.3.5.1.3.3.2 PAT Indirect Access Translation

The page-grained translation is named the indirect access. In this mode the translation vector is found in the internal 32-k entry physical address translation vector table at the index given by bits [26:12] of the input virtual address, and the DMM_PAT_VIEW_MAP_i CONT_x bit field references the internal physical address translation table to use. Because the DMM uses only one such table, in this mode the CONT_x bit field must be written as 0. See Figure 15-7.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 15-7. PAT Indirect Access Translation



Each entry of the PAT lookup table (LUT) is a 19-bit vector that replaces bits [30:12] of the input virtual address. The PAT index aimed at selecting the vector in the table consists of bits [26:12] of the input virtual address.

The mode associated to the transaction is used to define if the upper or lower half of the LUT is effectively used:

- If the mode is 8-, 16- or 32-bit, the lower part of the LUT (indexes 0x0000 to 0x7FFF; that is, lines 0 to 127) is used.
- If the mode is page, the upper part of the LUT (indexes 0x8000 to 0xFFFF; that is, ines 128 to 256) is used.

This means the PAT index used is the concatenation of 0 and address bits 12 to 26 in 8-, 16- or 32-bit mode, and the concatenation of 1 and address bits 12 to 26 in page mode.

Using different LUT indexes depending on the mode enables the user to define a larger tiled space, with the constraint that half of the space can be used only in 8-, 16- or 32-bit mode and the other half only in page mode. If the user wishes to preserve software compatibility with the case CONT_HGHT = 128, it is required to mirror the configuration for the lower half of the LUT on the upper half of the LUT. In that way, all views see the same address decoding through PAT.

15.2.3.5.1.3.3.3 PAT View Configuration

There are four different views in a DMM, each with its own DMM_PAT_VIEW_MAP_i register for defining the kind of address translation to perform.

The PAT view type of each mode is selected by the ACCESS_x bit field in the DMM_PAT_VIEW_MAP_i register, i being the index of the considered view. When this field is set to 1, the indirect access scheme is used; otherwise, the PAT performs the address translation in a direct way with the corresponding CONT_x vector.

When configuring a mode in a view to use the indirect access, the corresponding CONT_x bit field must be filled with 0.

15.2.3.5.1.3.3.4 PAT Address Translation LUT

The PAT LUT does not have the same geometry as the DMM container. The PAT LUT has 256 lines of 256 entries of 19 bits each. The geometry of the DMM container is 256 × 128 entries.

- The lower 128MiB are restricted for use with 8-, 16-, and 32-bit modes.
- The upper 128MiB are restricted for use with page mode.

See Figure 15-8.

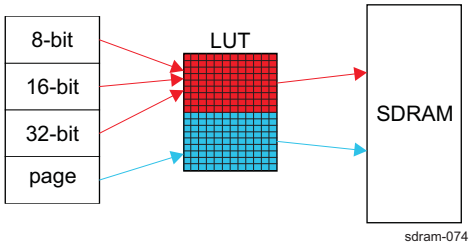
Figure 15-8. Physical Address Translation Table



15.2.3.5.1.3.3.5 Direct Access to the PAT Table Vectors

The PAT table is typically refilled with specialized DMA called refill engines. Some direct read and write access to the content of this table is granted when disabling the use of one or the other refill engine by writing 1 in the MODEi field of the DMM_PAT_CONFIG register that corresponds to the refill engine i to disable.

In this mode, often called the debug mode, the data read in or written to the DMM_PAT_DATA_i register corresponds to the vector in the PAT table, whose index is in the X0 and Y0 fields of the DMM_PAT_AREA_i register.

15.2.3.5.1.3.3.6 Automatic Refill Through the Refill Engines

See Section 15.2.4.1, *PAT Use Cases*.

15.2.3.5.2 DMM Transaction Flows

15.2.3.5.2.1 Nontiled Transaction Flow

Each nontiled interconnect transaction that reaches the DMM on a TILER port is subject to the same processing.

The TILER blocks consider separated request, data, and response paths. An overview of each path follows and more detailed information is in Section 15.2.3.5.3, *DMM Internal Macro-Architecture*.

On the request path, the flow consists of:

- Allocating a TILER response context for the timely generation of the appropriate responses
- Splitting 2D requests in a collection of 1D requests – TILER ports
- Splitting requests at DMM unit boundaries; the split granularity is provided by the LISA mapping registers
- Allocating an available buffer in the appropriate ROBIN, for both read and write requests
- In case of a write request, allocating and updating a TILER write context to direct the incoming write data into the relevant reordering buffer
- Generating the initiator-indexed priority extension by use of the PEG block

On the write data path, the flow consists of forwarding incoming data to the relevant reordering buffer in accordance with the corresponding TILER write context.

On the response path, responses are returned when:

- At least one response has entered each related buffer, in case of read requests.
- All related responses have returned from the SDRC, in case of write requests.
- No other previous pending response with the same tag exists.

15.2.3.5.2.2 Tiled Transaction Flow

Similarly, each tiled interconnect transaction that reaches the DMM is subject to the same processing.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The TILER blocks consider separated request, data, and response paths. An overview of each path follows, and more detailed information is in Section 15.2.3.5.3, *DMM Internal Macro-Architecture*.

On the request path, the processing phase consists of:

- Decoding the address to qualify whether the request targets the TILER or the memory directly
- Transforming TILER-specific requests to their natural representation; the address, width, and height are modified accordingly

On the request path, the generation phase consists of:

- Allocating a TILER response context for the timely generation of the appropriate responses
- Splitting malformed: The request stride differs from the container stride and from the double of this container stride – tiled 2D requests in a collection of 1D requests
- Splitting tiled requests at tile boundaries
- Performing the page-based address translation by use of the PAT block
- Allocating an available buffer in the appropriate ROBIN, for read and write requests
- In case of a write request, allocating and updating a TILER write context to direct the incoming write data into the relevant reordering buffer
- Generating the initiator-indexed priority extension by use of the PEG block

On the data path, any incoming data is transformed in accordance with the corresponding TILER write context and sent to the appropriate reordering buffer.

On the response path, responses are returned when:

- A minimal number of responses have entered the corresponding buffers, in case of read requests.
- All related responses have returned from the SDRCs, in case of write requests.
- No other previous pending response with the same tag exists.

15.2.3.5.3 DMM Internal Macro-Architecture

This section describes the DMM internal macro-architecture, specifically:

- Input request decoding
- PAT and synchronized translation table reloading
- Output request and response generation
- Memory mapping in the system addressing space, including interleaving
- Tag management
- Priority handling
- Contexts
- Maximum allowed burst size
- Reconstruction buffer dimensioning

15.2.3.5.3.1 LISA Description

The LISA is a full crossbar aimed at setting priorities, managing tags, and mapping memory.

The interconnect routes are:

- TILER requests on the ROBIN initiator nodes
- TILER write data on the ROBIN write buffers
- ROBIN read data to the relevant TILER initiators

The LISA block registers are DMM_LISA_MAP_i (where i = 0 to 3) and DMM_LISA_LOCK.

When two ROBINs are in use, the two ports are interleaved at a programmable boundary from 128 bytes or more (configurable with the DMM_LISA_MAP_i[19:18] SDRC_INTL bit field).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

15.2.3.5.3.2 PAT Description

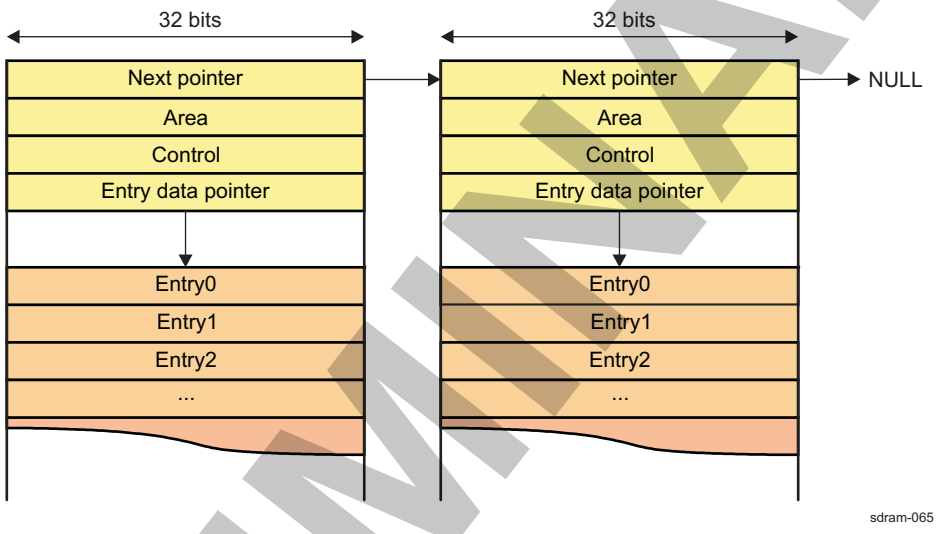
The PAT block maps physical pages to each TILER container page. The internal address translation memories used in the PAT block are designed with RFFs. It consists of:

- A memory-based LUT which has the same geometry as the container pages
- A refill engine for modifying entries in a given area of the internal LUT

A PAT descriptor is a singly-linked list node (see Figure 15-9) that contains:

- A description of the LUT area to reload
- A description of how to reload the defined LUT area
- A pointer to the location where the corresponding LUT entries are stored

Figure 15-9. PAT Descriptors



PAT descriptors are chained and processed until a NULL pointer is encountered. The PAT bank allocation scheme allows the updating of four consecutive entries of a line in a single cycle regardless of the refilling orientation.

The PAT descriptor structure directly maps the following registers (where i = 0 to 3):

- DMM_PAT_DESCR_i
- DMM_PAT_AREA_i
- DMM_PAT_CTRL_i
- DMM_PAT_DATA_i

The PAT refill engine can be started either of the following:

- Filling manually all the necessary registers:
  - DMM_PAT_AREA_i with the (x0, y0) (x1, y1) area definition
  - DMM_PAT_DATA_i with the physical address of the corresponding area entry table
  - DMM_PAT_CTRL_i[6:4] DIRECTION bit field with the relevant (S, Y, X) direction of the area refill
  - DMM_PAT_CTRL_i[0] START bit with 1
- Writing the physical address of a memory-mapped PAT descriptor in DMM_PAT_DESCR_i register, which updates:
  - DMM_PAT_AREA_i with the area value of the descriptor
  - DMM_PAT_DATA_i with the data value of the descriptor
  - DMM_PAT_CTRL_i with the control value of the descriptor
  - DMM_PAT_DESCR_i with the next value of the descriptor

The data part of the PAT refill starts only when the DMM_PAT_CTRL_i[0] START bit is asserted.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The DMM_PAT_STATUS_i register can be used to determine whether the process has completed without errors.

15.2.3.5.3.3 PEG Description

The PEG is a dynamic software-programmable, initiator-indexed table of priorities. Its unique role is to bind a priority to an initiator on the fly. The mapping of each initiator to the table (split into eight registers) is based on its 6-MSB group ConnID (see Section 14.2.3.2.3, *Master NIU Identification*, in Chapter 14, *Interconnect*).

When an interconnect request enters the DMM, its priority is extracted from the PEG LUT.

The 64 priority entries are software-programmable with the DMM_PEG_PRIO_k register. A priority of 0 defines the highest priority and a priority of 7 defines the lowest priority. At reset, all priorities are set to 4.

These registers are each split into eight 4-bit fields, each field mapping an entry of the LUT with:

- The 3-bit priority coded on the 3 least-significant bits (LSBs): P field
- A $\overline{W}$ field-specific active-low local write enable bit, always read as 0, on the MSB. The role of the $\overline{W}$ bit is to allow the modification of a single entry without requiring a read-modify-write sequence. Because its $\overline{W}$ bits are always read as 0, writing back the modified register updates all priority fields of the register.

Table 15-9 lists the initiator ConnIDs that are mapped to PEG priority register fields (P/W).

Table 15-9. ConnIDs vs PEG Priority Register Fields

Registers	P0/W0	P1/W1	P2/W2	P3/W3	P4/W4	P5/W5	P6/W6	P7/W7
DMM_PEG_PRIO_0	0	1	2	3	4	5	6	7
DMM_PEG_PRIO_1	8	9	10(0xA)	11(0xB)	12(0xC)	13(0xD)	14(0xE)	15(0xF)
DMM_PEG_PRIO_2	16(0x10)	17(0x11)	18(0x12)	19(0x13)	20(0x14)	21(0x15)	22(0x16)	23(0x17)
DMM_PEG_PRIO_3	24(0x18)	25(0x19)	26(0x1A)	27(0x1B)	28(0x1C)	29(0x1D)	30(0x1E)	31(0x1F)
DMM_PEG_PRIO_4	32(0x20)	33(0x21)	34(0x22)	35(0x23)	36(0x24)	37(0x25)	38(0x26)	39(0x27)
DMM_PEG_PRIO_5	40(0x28)	41(0x29)	42(0x2A)	43(0x2B)	44(0x2C)	45(0x2D)	46(0x2E)	47(0x2F)
DMM_PEG_PRIO_6	48(0x30)	49(0x31)	50(0x32)	51(0x33)	52(0x34)	53(0x35)	54(0x36)	55(0x37)
DMM_PEG_PRIO_7	56(0x38)	57(0x39)	58(0x3A)	59(0x3B)	60(0x3C)	61(0x3D)	62(0x3E)	63(0x3F)

Although this priority information is generated before entering the LISA block, it is not used internally in the local interconnect arbitration but is forwarded to the EMIF as MReqInfo, where it indicates the command priority.

It is also possible to give a priority for the internal PAT engine through the DMM_PEG_PRIO_PAT register.

15.2.3.5.3.4 LISA Interconnect Arbitration

When Mflag[i][63:0] ≠ 0 is signaled at TILERi or both TILERs, the transactions of TILERi or both TILERs form an additional new group called the high priority group. Within this group, reads and writes are sorted and arbitrated the same way as in the normal priority group. Arbitration between transactions out of the high priority group and out of the normal priority group is based on a weighted round-robin algorithm. Weight is software selectable using the DMM_EMERGENCY[20:16] WEIGHT bit field. Weight selection is considered static (that is, behavior is undefined when software changes the weight, and DMM is not empty of transaction).

The counter that is implemented to support the weighted round-robin is enabled as long as emergency signaling is present. The counter increments by one each time a command (from the normal or the high priority group) is pushed to ROBIN. The counter wraps on DMM_EMERGENCY[20:16] WEIGHT value. One command from the normal priority group is serviced in any of the following scenarios:

- The counter is enabled and wraps.
- The counter is enabled, has not reached its wrap value, and no command is queued in the high priority group (a case where one device module is signaling emergency but its requests have not yet reached

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

the TILERs).

- The counter is disabled.

Setting the DMM_EMERGENCY[0] ENABLE bit to 1 enables the emergency arbitration scheme.

NOTE: It is recommended to set the DMM_EMERGENCY[0] ENABLE bit to 1, and the DMM_EMERGENCY[20:16] WEIGHT bit to 0x8. This provides better and faster recovery behavior, and benefits system performance.

15.2.3.5.3.5 ROBIN Description

The ROBIN is a block that provides some working buffering for converting data and responses to-and-from between raster and tiled organizations, and a master port to connect to the EMIF.

The ROBIN block:

- Forwards requests
- Writes data and buffers responses
- Keeps write data ordering
- Performs intraword tiling and orientation transforms
- Handles tags

15.2.3.5.3.6 TILER Description

The main function of the TILER is request conversion caused by tiling.

The TILER block:

- Decodes the address to qualify whether the request targets the TILER or the memory directly
- Converts TILER-specific requests to their natural representation; address, width, and height are modified accordingly
- Allocates an internal response context for the timely generation of appropriate responses
- Splits tiled requests at tile boundaries and not-tiled requests at DMM atomic section boundaries
- Requests the page-based address translation
- Requests buffer allocation in the appropriate ROBIN
- In case of a write request, allocates and updates an internal write context to direct the incoming write data into the relevant reordering buffer

The interdependent tilingand isometric transform concepts introduced in the TILER are described in the following section.

15.2.3.6 TILER

15.2.3.6.1 TILER Concepts

This section describes the concepts behind the TILER transforms, through a top-down approach starting from the main object container.

15.2.3.6.1.1 TILER Rationale

This section is a synthesis of all TILER concepts, giving one rule per TILER structure level.

Figure 15-10 shows the TILER address space structure for tiled modes.

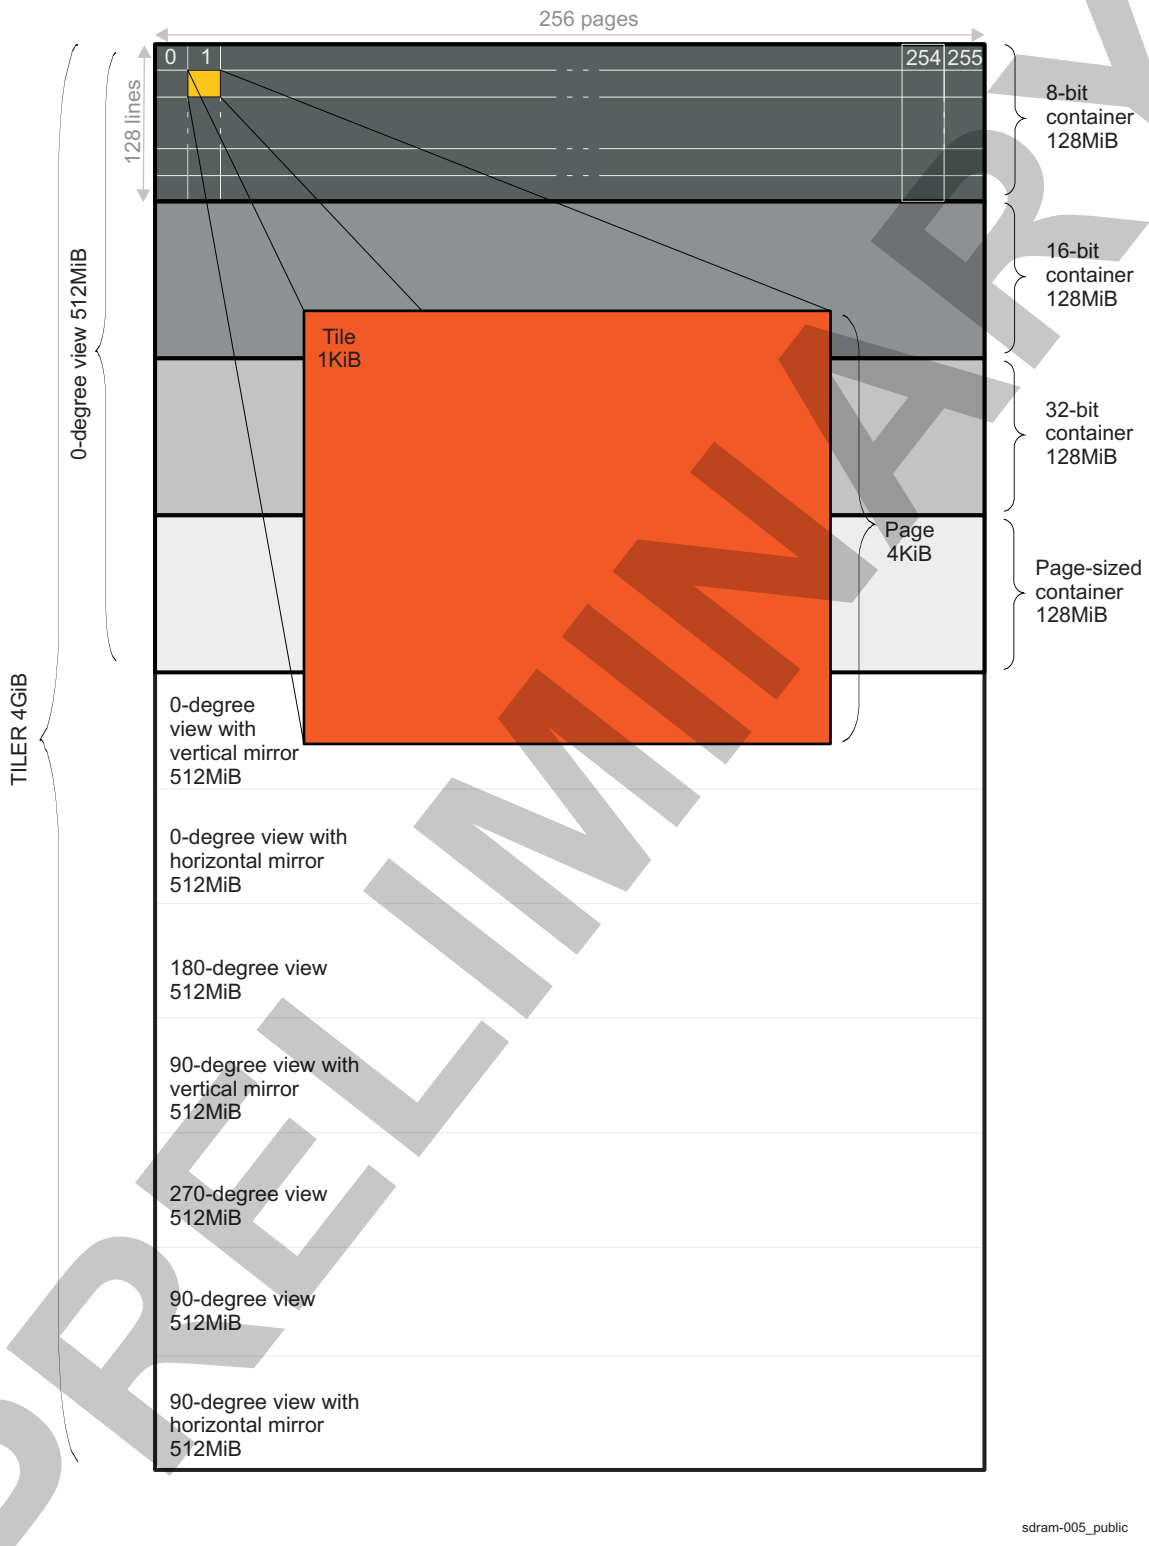
Figure 15-10. TILER Address Space Structure for Tiled Modes



PRELIMINARY

15.2.3.6.1.1.1 The TILER is a 4-GiB Virtual Address Space Composed of Eight Views

There is one view for each of the eight possible ways of scanning a frame-buffer:

- From left to right and then from top to bottom

Copyright © 2013, Texas Instruments Incorporated

- From right to left and then from top to bottom
- From left to right and then from bottom to top
- From right to left and then from bottom to top
- From top to bottom and then from left to right
- From top to bottom and then from right to left
- From bottom to top and then from left to right
- From bottom to top and then from right to left

15.2.3.6.1.1.2 A View is a 512-MiB Virtual Address Space Composed of Four Containers

There is one container per element size to allow correct access patterns in any of the eight possible orientations. The container is the entity where all objects of a given element type are allocated.

The element is the entity of maximum size (8, 16, 32 bits, or page-sized), which is invariant in any orientation.

15.2.3.6.1.1.3 A Container is a 128-MiB Virtual Address Space

A container is composed of an array of 128 lines of 256 pages of 4kiB each.

The page defines the granularity of physical memory allocation through a PAT unit – MMU.

15.2.3.6.1.1.4 A Page is a 4-kiB Virtual Address Space

A page is composed of two lines. Each line consists of two tiles.

15.2.3.6.1.1.5 A Tile is a 1-kiB Address Space

The tile is designed to offer bidimensional data locality in a single SDRAM page. In this respect, it is sized to 1kiB; that is, to the size of the smallest SDRAM page.

15.2.3.6.1.2 TILER Modes

The TILER supports three major modes, bypass, page, and tiled. Each mode has a specific output request generation.

15.2.3.6.1.2.1 Bypass Mode

This mode is transparent from the TILER perspective. However, from the DMM perspective:

- 2D block bursts are broken down on a line basis in a set of incremental bursts.
- Incremental bursts, including those issued by a 2D block burst breakdown, are split at the DMM atomic unit of the section hit by the burst at:
  - The interleaving granularity of the section (128, 256, or 512 bytes) in interleaved sections
  - 1-kiB boundary in noninterleaved sections

15.2.3.6.1.2.2 Page Mode

This mode uses the DMM address translation mechanism for nontiled accesses. In this respect it is similar to bypass mode:

- 2D block bursts are broken down on a line basis in a set of incremental bursts.
- Incremental bursts, including those issued by a 2D block burst breakdown, are split at:
  - The interleaving granularity of the section (128, 256, or 512 bytes) in interleaved sections
  - 1-kiB boundary in noninterleaved sections

15.2.3.6.1.2.3 Tiled Mode

Tiled mode has two major breakdown algorithms:

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- One for well-formed 2D block requests that conform to the orientation, mode, and stride listed in Table 15-10
- One for 1D incremental requests and ill-formed 2D block requests

Table 15-10. Well-Formed Tiled Mode 2D Block Requests

Orientation			Mode		Stride	Description
S	$\overline{Y}$	$\overline{X}$	M1	M0	(bytes)	
0	x	x	0	0	16,384	Plain access to an 8-bit progressive frame in 0 or 180 degrees
					32,768	Field access to an 8-bit interlaced frame 0 or 180 degrees
			0	1	32,768	Plain access to a 16-bit progressive frame in 0 or 180 degrees
					65,536	Field access to a 16-bit interlaced frame 0 or 180 degrees
			1	0	32,768	Plain access to a 32-bit progressive frame in 0 or 180 degrees
					65,536	Field access to a 32-bit interlaced frame 0 or 180 degrees
1	x	x	0	0	8192	Plain access to an 8-bit progressive frame in 90 or 270 degrees
					16,384	Field access to an 8-bit interlaced frame 90 or 270 degrees
			0	1	8192	Plain access to a 16-bit progressive frame in 90 or 270 degrees
					16,384	Field access to a 16-bit interlaced frame 90 or 270 degrees
			1	0	16,384	Plain access to a 32-bit progressive frame in 90 or 270 degrees
					32,768	Field access to a 32-bit interlaced frame 90 or 270 degrees

Similar to the bypass and page modes, ill-formed 2D block requests are broken down on a line basis in a set of incremental bursts. In tiled mode, however, these incremental virtual bursts do not translate to 1D physical burst requests.

15.2.3.6.1.3 Object Container Definition

The object container is the unique addressable entry point of the TILER. It is a 128-MiB virtual address space, where all objects of a same kind and orientation are allocated.

Four main types of containers are present in the TILER, each referred by a mode:

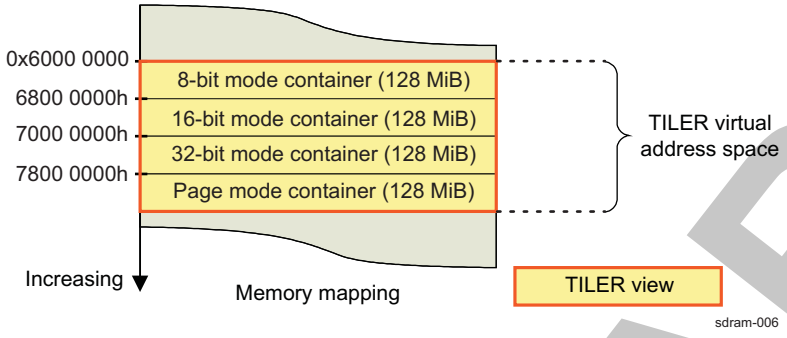
- 8-bit element mode, for efficiently accessing bidimensional arrays of 8-bit data
- 16-bit element mode, for efficiently accessing bidimensional arrays of 16-bit data
- 32-bit element mode, for efficiently accessing bidimensional arrays of 32-bit data
- Page mode, for efficient 1D accesses

Figure 15-11 shows the TILER object containers and views.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 15-11. TILER Object Containers and Views

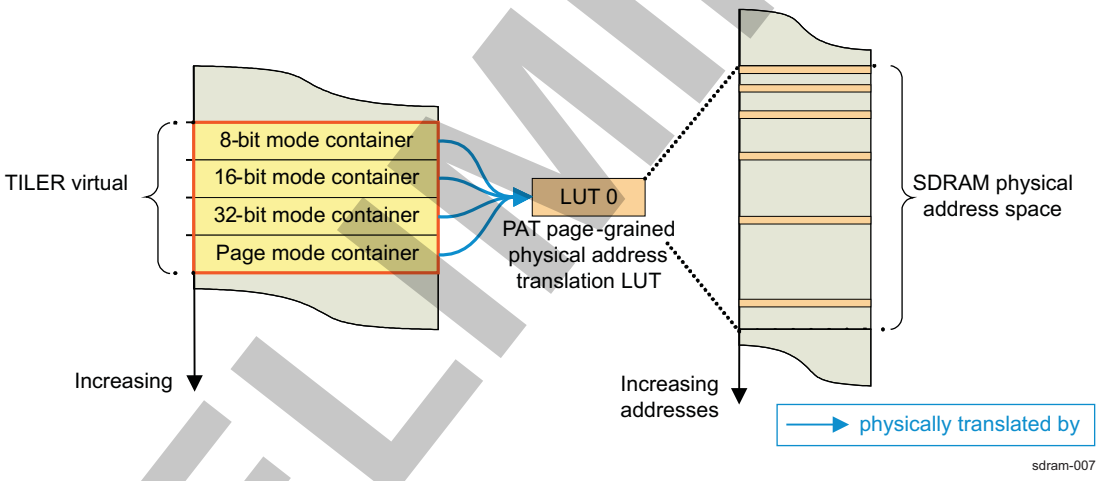


The 512-MiB virtual address space composed of four 128-MiB object containers of different modes is called a view. Because eight orientations are available per mode, the TILER actually manages 32 kinds of containers.

The physical memory footprint of a 512-MiB TILER view is directly subject to the nature of the PAT unit.

A unique PAT LUT is instantiated in the DMM. This table is shared by all TILER modes. Hence, each of the four modes cannot be given its own private page-grained PAT LUT. A maximum of 128MiB of objects among all TILER modes can be managed as shown in Figure 15-12.

Figure 15-12. TILER Memory Footprint With PAT and Shared Physical Address Translation LUT



Although each of the four modes has its own separate virtual 128-MiB object container, these containers are all mapped to the same piecewise 128-MiB physical address space, and are then not physically separated. Consequently, a memory-related system constraint is that no more than 128-MiB of objects can be available simultaneously in a TILER view.

NOTE: Software must ensure that any object allocated in a mode does not physically overlap with any other object, even in another mode.

15.2.3.6.1.4 Page Definition

A TILER page defines the granularity of object allocation in virtual TILER containers.

Because the subpage structure is mode-specific, the page is the smallest granularity common to all modes, making it the granularity to consider in the TILER resource manager for object allocation.

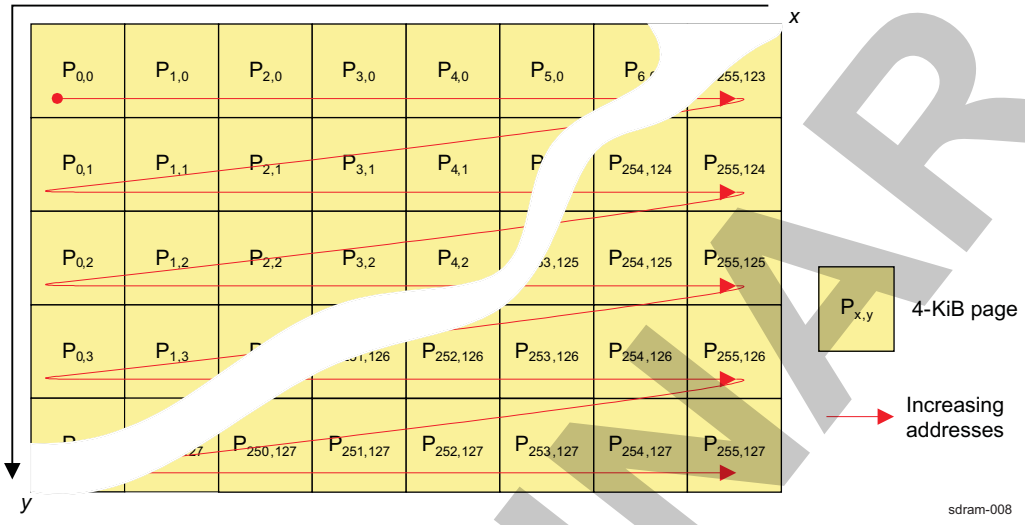
PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

15.2.3.6.1.4.1 Container Geometry With 4-kiB Pages

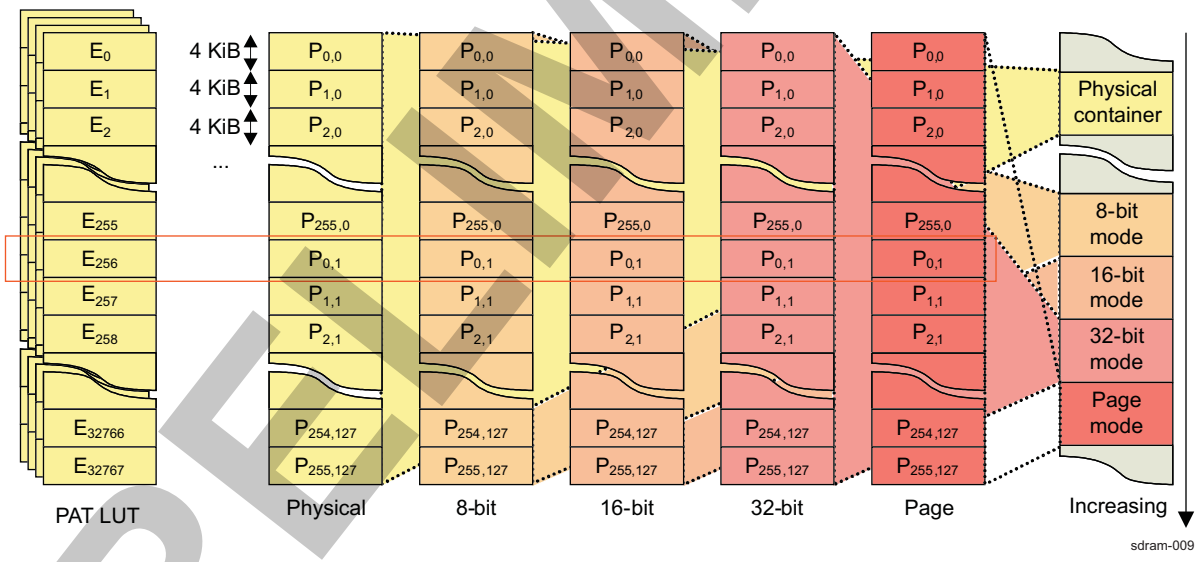
Because the size of the page is 4kiB, any 128-MiB object container is a set of 32,768 pages, organized in an array of 256 columns and 128 rows, as shown in Figure 15-13.

Figure 15-13. Object Container Geometry With 4-kiB Pages



This array of pages is mapped to the system address space, as shown in Figure 15-14.

Figure 15-14. TILER Page Mapping When Using 4-kiB Pages



In any 128-MiB object container, the 4-kiB page Px,y at column x (where 0 =< x < 256) and row y (where 0 =< y < 128), is found at an offset of 4096.(x+256.y) bytes from the base address of the related object container.

Similarly, the page Px,y at column x (where 0 =< x < 256) and row y (where 0 =< y < 128), is translated by the LUT entry Ex+256.y found at the index x+256.y.

15.2.3.6.1.4.2 Container Geometry and Page Mapping Summary

The TILER has a page size of 4096 bytes. The page $P_{x,y}$:

- Has max_x = 256 and max_y = 128
- Is found at an offset of 4096.(x + max_x.y) bytes from the base address of the related object container
- Is translated by the entry at the index (x + max_x.y) of the LUT

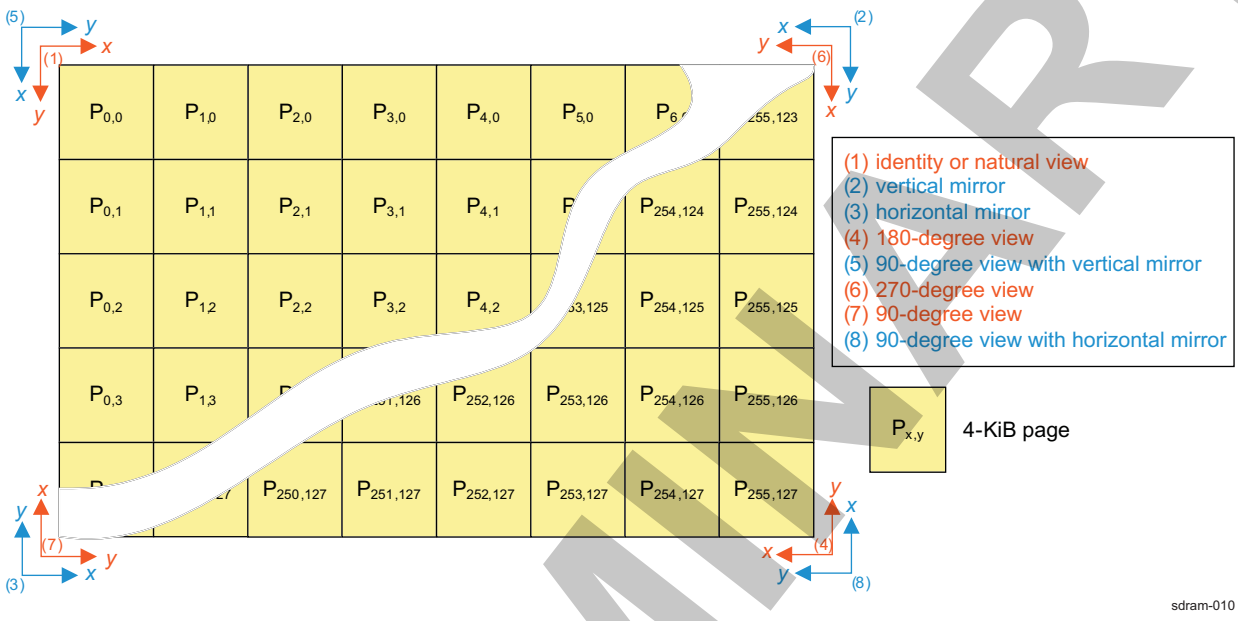
15.2.3.6.1.5 Orientation

This section describes the eight on-the-fly orientation-related isometric transforms, which correspond to all available changes of orthonormal basis in the bidimensional space of the TILER container.

Figure 15-15 shows isometric transforms in the TILER container

Figure 15-15. Isometric Transforms in the TILER Container



Mathematically speaking, all these transforms correspond to the composition of a 0-, 90-, 180-, or 270-degree rotation with an optional reflection. The nature of this orientation is based on the three following binary parameters:

- *X* to change the direction of the $_{x}$ axis of the TILER container
- *Y* to change the direction of the $_{y}$ axis of the TILER container
- *S* to swap the modified $_{x}$ and $_{y}$ axis

Hereafter in this document the term orientation refers to any composition of a "quadrant" rotation with an optional horizontal (flip-flop) or vertical mirroring.

15.2.3.6.1.6 Tile Definition

A tile is a subdivision of a page that is aimed at:

- Representing a 2D block to better balance accesses in both directions
- Ensuring that any tiled access that fits within a tile is made atomic in the SDRC and fits in a single SDRAM memory page
- Minimizing the number of SDRAM page openings per 2D block transfer

The tile is defined as a 1-kiB 2D block, and a 4-kiB page as an array of two lines of two tiles each.

When the considered page is in an interleaved DMM section, it is necessary that:

- The DMM memory interleaving size of tiled accesses is set to 1kiB (a tile size) so that any tiled request that fits within a tile, fits in a single SDRAM memory page.
- Any request that spans two or four tiles is distributed on a maximum number of SDRCs.

15.2.3.6.1.7 TILER Virtual Addressing

The TILER can be virtually accessed in four different modes: 8-, 16-, 32-bit, and page modes. Each mode defines the element granularity to apply isometric transforms, as summarized in Table 15-11.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

Table 15-11. Coding and Description of TILER Modes

Mode	Name	Granularity (Element Size)
0	8-bit tiled mode	8 bits
1	16-bit tiled mode	16 bits
2	32-bit tiled mode	32 bits
3	Page mode	4096 bytes

For instance, making a vertical mirror of a 16-byte horizontal line that contains the word 000102030405060708090A0B0C0D0E0Fh, leads to:

- 0F0E0D0C0B0A09080706050403020100h in 8-bit tiled mode
- 0E0F0C0D0A0B08090607040502030001h in 16-bit tiled mode
- 0C0D0E0F08090A0B0405060700010203h in 32-bit tiled mode
- 000102030405060708090A0B0C0D0E0Fh in page mode – unchanged because the element granularity is 4 KiB

Besides, because each of the eight orientations is available for any of the four modes, the TILER has 32 addressing possibilities (see Table 15-12).

Table 15-12. Coding and Description of TILER Orientations

S	$\overline{Y}$	$\overline{X}$	Description	Alternate description
0	0	0	0-degree view	Natural view
0	0	1	0-degree view with vertical mirror	180-degree view with horizontal mirror
0	1	0	0-degree view with horizontal mirror	180-degree view with vertical mirror
0	1	1	180-degree view	
1	0	0	90-degree view with vertical mirror	270-degree view with horizontal mirror
1	0	1	270-degree view	
1	1	0	90-degree view	
1	1	1	90-degree view with horizontal mirror	270-degree view with vertical mirror

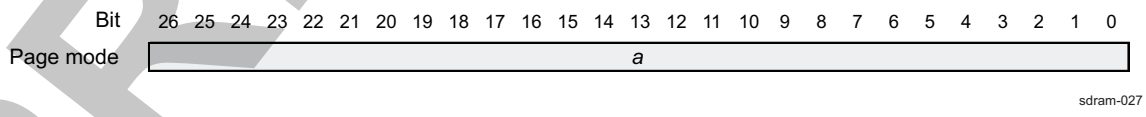
15.2.3.6.1.7.1 Page Mode Virtual Addressing and Characteristics

When used in page mode, the 128-MiB TILER space is seen as an orientation-specific sequence of 32,768 pages of 4kiB each. The access sequence inside a page is left unchanged.

Therefore, in page mode, the TILER is accessed similarly to any 128-MiB memory, with a 27-bit byte-based address.

NOTE: From here forward, the address is noted as *a* (see Figure 15-16).

Figure 15-16. Page Mode Virtual Addressing



15.2.3.6.1.7.2 Tiled Mode Virtual Addressing and Characteristics

When used in tiled mode, the 128-MiB TILER space is seen as a giant frame-buffer, the container. The addressing and characteristics of this giant frame-buffer depend on:

- The tiled mode, which defines the considered atomic element size
- The orientation, which potentially swaps its x and y axis, and hence the container geometry

Table 15-13 summarizes the container characteristics in tiled mode.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

Table 15-13. Tiled Mode Container Characteristics

Orientation			Element Size (Bits)	Width (Elements)	Height (Elements)	Stride (Bytes)	
S	$\bar{Y}$	$\bar{X}$				Progressive	Interlaced
0	x	x	8	16,384	8192	16,384	32,768
			16	16,384	4096	32,768	65,536
			32	8192	4096	32,768	65,536
1	x	x	8	8192	16,384	8192	16,384
			16	4096	16,384	8192	16,384
			32	4096	8192	16,384	32,768

As a result, the coordinate (x_0, y_0) of a pixel in an oriented view is translated in a virtual address, as shown in Figure 15-17 and Figure 15-18.

Figure 15-17. Tiled Mode Addressing in 0- or 180-Degree Orientation (S = 0)

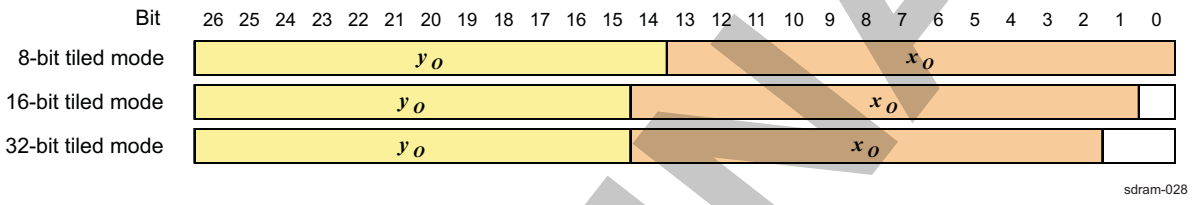


Figure 15-18. Tiled Mode Addressing in 90- or 270-Degree Orientation (S = 1)

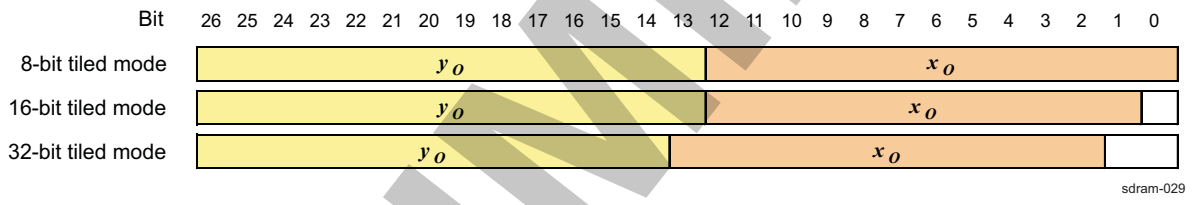

15.2.3.6.1.7.3 Element Ordering in the TILER Container

This section describes how elements (8-, 16-, or 32-bit data or a 4-kiB page) are ordered in the container. In other words, this section describes how the path of incrementing virtual addresses is mapped in the container.

Regardless of the mode, and hence the element size, the sequence for ordering the elements in their related container is strictly similar and depends only on the related orientation. In other words:

- Mode is concerned with element granularity.
- Orientation is concerned with change of orthornormal basis for ordering the elements in the mode-specific container.

A corollary to the previous statements is that in a given mode the internal structure of an element is unchanged regardless of the orientation. In page mode for instance, the offset of a word inside a page is invariant by orientation; the content of a page is always accessed in the same manner.

In the following sections, the natural container orthonormal basis is referenced as:

$$(\vec{x}_N, \vec{y}_N)$$

sdram-030

and the oriented orthonormal basis is referenced as:

$$(\vec{x}_O, \vec{y}_O)$$

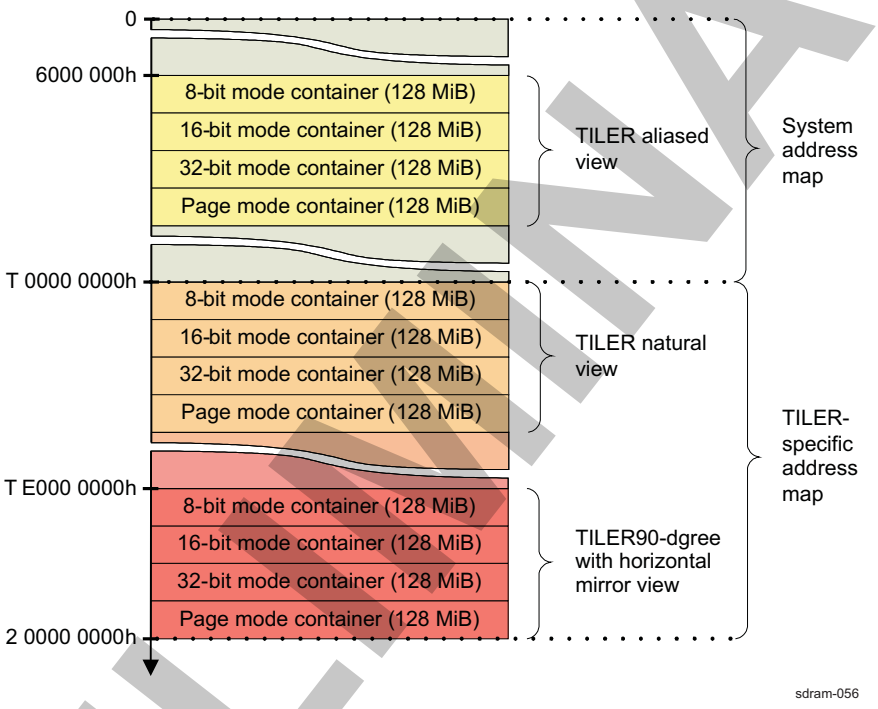
15.2.3.6.2 TILER Macro-Architecture

The TILER requires a 4-GiB addressing space to map its 128-MiB physical container in four modes and eight orientations. Because its addressing space alone fills the 4-GiB global system address map, the TILER addressing space cannot enter as-is into the system address map. Besides, putting in place a register-based mechanism per initiator to specify the orientation of the following accesses and then reducing the TILER addressing space to a single 512-MiB view is not an option; this is because most of the bandwidth-hungry initiators require simultaneous accesses to the TILER container in different views.

As a result, 32 bits are not enough to address all these requests, because the TILER port must convey not only virtually addressed requests to the "oriented" TILER containers but also physically addressed requests to the attached SDRCs. A thirty-third address bit is necessary to distinguish the two separated address maps, as shown in Figure 15-35.

Figure 15-35. TILER Port Address Map



Still, having separated systems and TILER-specific address maps is not sufficient. In a system many existing and external IP blocks still rely on a 32-bit address and would then be limited to one or the other 4-GiB addressing space. To overcome this limitation, one 512-MiB view is aliased in the system address map as (see Table 15-14 and Figure 15-36).

Table 15-14. TILER Aliased View in the L3 Interconnect Mapping

Start Address (hex)	End Address (hex)	Size
0x6000_0000	0x7FFF_FFFF	512 MiB

From all incoming requests, TILER requests are filtered as having an address that fits one of the following:

- The address format in the TILER-specific address map given in Table 15-15
- The address format of the aliased view in the system address map given in Table 15-16

Other requests are forwarded directly to the SDRC in TILER bypass mode.

Table 15-15. Address Format in the TILER-Specific Address Map

32	31	30	29	28	27	26 ... 4	3 ... 0

PRELIMINARY

Table 15-16. Address Format of the TILER Aliased View in the System Address Map

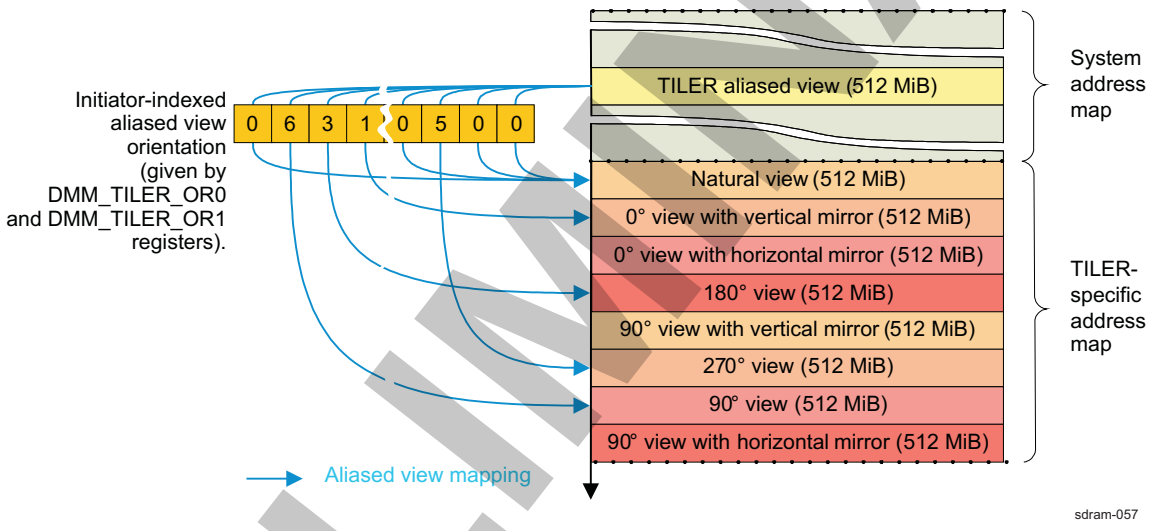
32	31	30	29	28	27	26 ... 4	3 ... 0
T	TILER aliasing			Mode		Virtual address	
0	0	1	1	M1	M0	A26 ... A4	0

In these address formats:

- The thirty-third bit, noted T, is aimed at distinguishing the standard 4-GiB system address map from the 4-GiB TILER-specific address map.
- The orientation bits, noted S, $\overline{Y}$, and $\overline{X}$, define the request orientation, as specified in Table 15-12.
- The mode bits, noted M1 and M0, define the request mode, as specified in Table 15-11.
- The remaining 27 bits, noted A0 to A26, define the mode and orientation specific virtual address, as defined in Figure 15-16, Figure 15-17, and Figure 15-18.

The orientation of the aliased TILER view is extracted from an initiator-indexed LUT, as shown in Figure 15-36.

Figure 15-36. TILER Aliased View Orientation



As shown in Figure 15-36, an internal initiator-indexed LUT stores the current orientation of the aliased view for each initiator.

When an interconnect request hits the TILER aliased view in the system address map, the request initiator orientation is extracted from the LUT and the request address is translated according to this orientation: the T bit is set and bits [31:29] are replaced with the orientation.

Regarding the dimensioning of this LUT, given that initiators simultaneously accessing multiple views use the TILER-specific address map, and many initiators do not need to access any view or can be restricted to accessing only the natural view, only a limited number of initiators are likely to dynamically modify the orientation of its aliased TILER view.

The orientation LUT is limited to 16 entries. These 16 orientation entries are mapped on the two 32-bit DMM_TILER_OR0 and DMM_TILER_OR1 registers.

The first eight entries of the LUT are mapped in the DMM_TILER_OR0 register, and the last eight entries are mapped in the DMM_TILER_OR1 register. Therefore, given an index x, the orientation related to this index is given in the ORx field.

Each of these registers is split into eight 4-bit fields, each field mapping an entry of the LUT with:

- An S, $\overline{Y}$, $\overline{X}$ orientation code on the 3 LSBs
- An $\overline{W}$ field-specific active-low local write-enable bit, always read as 0, on the MSB.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

The registers fields that correspond to initiators that do not need any dynamic configuration of their aliased view orientation must be specified as reserved fields, and only written with zeros.

The $\overline{W}$ bit allows the modification of a single entry without requiring a read-modify-write sequence. This approach is then more accommodating:

- In a system where multiple initiators can modify their own fields in the registers
- With initiators unable to make the read-modify-write sequence, such as DMA

Still, the $\overline{W}$ bit is active-low to keep the compatibility with the usual read-modify-write sequence. When reading an aliased view orientation register, because all its $\overline{W}$ bits are read as 0, if these bits are untouched by the modification—as they should be—writing back the modified register updates all orientation fields of the register.

15.2.3.6.3 TILER Guidelines for Initiators

15.2.3.6.3.1 Buffered Raster-Based Initiators

15.2.3.6.3.1.1 Buffer Size

The necessary minimum buffer size depends on the SDRAM prefetch size and on initiator support in terms of the following:

- Element size
- Orientation
- Maximum number of elements per line in all supported element sizes and orientations

Let N be the maximum number of elements per line for a given mode (element size) and orientation, P be the SDRAM memory prefetch size in bytes, and *max* be the function returning the maximum of the two parameters. The minimum necessary line buffer size to handle all resolutions in a given mode and orientation is listed in Table 15-17.

Table 15-17. Minimum Buffer Size to Efficiently Handle Lines of up to N Elements

	0- or 180- Degree Orientation (S = 0)	90- or 270-Degree Orientation (S = 1)
8-bit mode	4 × N bytes	*max* (4,P/4) × N bytes
16-bit mode	None	*max* (8,P/2) × N bytes
32-bit mode	None	*max* (8,P/2) × N bytes

This minimal buffer size can be reached only with an advanced FIFO management scheme. The standard ping-pong buffer requires twice this buffer size.

NOTE: Given their nature, field accesses to an interlaced frame-buffer require buffers twice as small as in the standard progressive case.

For instance, an initiator that must handle only a single progressive frame-buffer in any orientation of:

- Up to 1920 × 1080 in YUV4:2:0
- Up to 1600 × 1200 in 16-bit RGB565
- Up to 800 × 600 in 32-bit ARGB

requires a line buffer of at least 15,360 bytes because:

- 4 × 1920 + 4 × 2960 = 15,360 bytes required for a 3-plane YUV4:2:0 frame of 1920 × 1080
- 4 × 1920 + 8 × 960 = 15,360 bytes required for a 2-plane YUV4:2:0 frame of 1920 × 1080
- 8 × 1600 = 12,800 bytes required for a 16-bit RGB565 frame of 1600 × 1200
- 8 × 800 = 6400 bytes required for a 32-bit ARGB frame of 800 × 600

and a line buffer of at least 30,720 bytes when using a simple ping-pong buffer scheme.

PRELIMINARY

15.2.3.6.3.1.2 Performance

Table 15-18 gives the ratio of effective data to transferred data at the external memory interface for buffered raster-based initiators in each mode and orientation, when using an up-to-32-bit DDR, lpDDR, or lpDDR2 SDRAM, or an up-to-16-bit DDR2 memory.

Table 15-18. Memory Data Payload for Buffered Raster-Based Initiators on Up-to-32-Bit DDR, lpDDR, or lpDDR2

	0- or 180-Degree Orientation (S = 0)		90- or 270-Degree Orientation (S = 1)	
	Progressive	Interlaced	Progressive	Interlaced
8-bit mode	100%	100%	100%	50%
16-bit mode	100%	100%	100%	50%
32-bit mode	100%	100%	100%	50%
Page mode	100%	N/A	100%	100%

When using 32-bit DDR, lpDDR, or lpDDR2 SDRAMs, or 16-bit DDR, DDR2, lpDDR, or lpDDR2 memories, whenever all previous guidelines are fulfilled, there is no penalty for these initiators to access a tiled object in any orientation, except for accesses to an interlaced frame in 90- or 270-degree orientation where the memory bandwidth is twice the requested bandwidth.

When using up-to-32-bit DDR, lpDDR, lpDDR2, or up-to-16-bit DDR2 SDRAMs, all accesses, except interlaced accesses in a 90- or 270-degree orientation, are equally efficient and offer the full possible memory bandwidth.

Because of its progressive nature, page mode does not introduce any performance hit.

Table 15-19 lists the ratio of effective data-to-transferred data at the external memory interface for the buffered raster-based initiators in each mode and orientation when using a 32-bit DDR2 or DDR3 memory.

Table 15-19. Memory Data Payload for Buffered Raster-Based Initiators on 32-Bit DDR2 or DDR3

	0- or 180-Degree Orientation (S = 0)		90- or 270-Degree Orientation (S = 1)	
	Progressive	Interlaced	Progressive	Interlaced
8-bit mode	100%	50%	100%	50%
16-bit mode	100%	50%	100%	50%
32-bit mode	100%	50%	100%	50%
Page mode	100%	N/A	100%	100%

When using 32-bit DDR2 or DDR3 SDRAMs, whenever all previous guidelines are fulfilled, there is no penalty for these initiators to access a tiled object in any orientation, except for accesses to an interlaced frame in any orientation where the memory bandwidth is twice the requested bandwidth.

When using DDR2 or DDR3 SDRAMs, all accesses, except interlaced accesses, are equally efficient and offer the full possible memory bandwidth.

Similarly, page mode does not introduce any performance hit.

15.2.4 DMM Use Cases and Tips

15.2.4.1 PAT Use Cases

Five ways to use PAT are:

- Simple manual area refill: Section 15.2.4.1.1
- Single auto-configured area refill: Section 15.2.4.1.2
- Chained auto-configured area refill: Section 15.2.4.1.3
- Synchronized auto-configured area refill: Section 15.2.4.1.4
- Cyclic synchronized auto-configured area refill: Section 15.2.4.1.5

NOTE: PAT refill area must be fully contained within either the LUT lower half or the LUT upper half. It must not span over both areas. That is, y0 MS

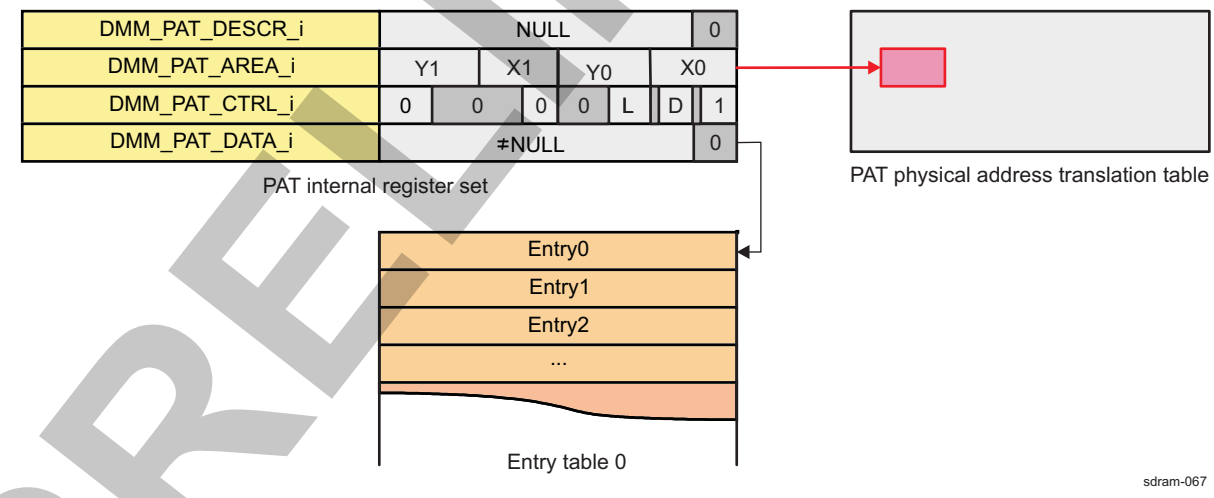
bit y0[7] must be equal to y1 MSbit y1[7] when defining the area descriptor.

15.2.4.1.1 Simple Manual Area Refill

The following must be performed to create a 16-byte aligned memory-mapped entry table containing all entries of the defined area (see Figure 15-37):

1. Write the DMM_PAT_AREA_i register with the relevant (x0, y0) (x1, y1) area definition.
2. Write the DMM_PAT_DATA_i register with the physical address of the created entry table.
3. Write the DMM_PAT_CTRL_i register with the requested refill direction and assert the DMM_PAT_CTRL_i[0] START bit with the requested refill direction D and with the LUT ID L if multiple LUTs are present in the system.
4. The refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 15-37. Simple Manual Area Refill Scheme



15.2.4.1.2 Single Auto-Configured Area Refill

The following must be performed to create a 16-byte aligned memory-mapped entry table containing all entries of the defined area (see Figure 15-38):

1. Create a 16-byte aligned memory-mapped descriptor structure where:
   - The next field is set to NULL.
   - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
   - The ctrl field is set with the requested direction D, with the requested LUT ID L if multiple LUTs are

PRELIMINARY

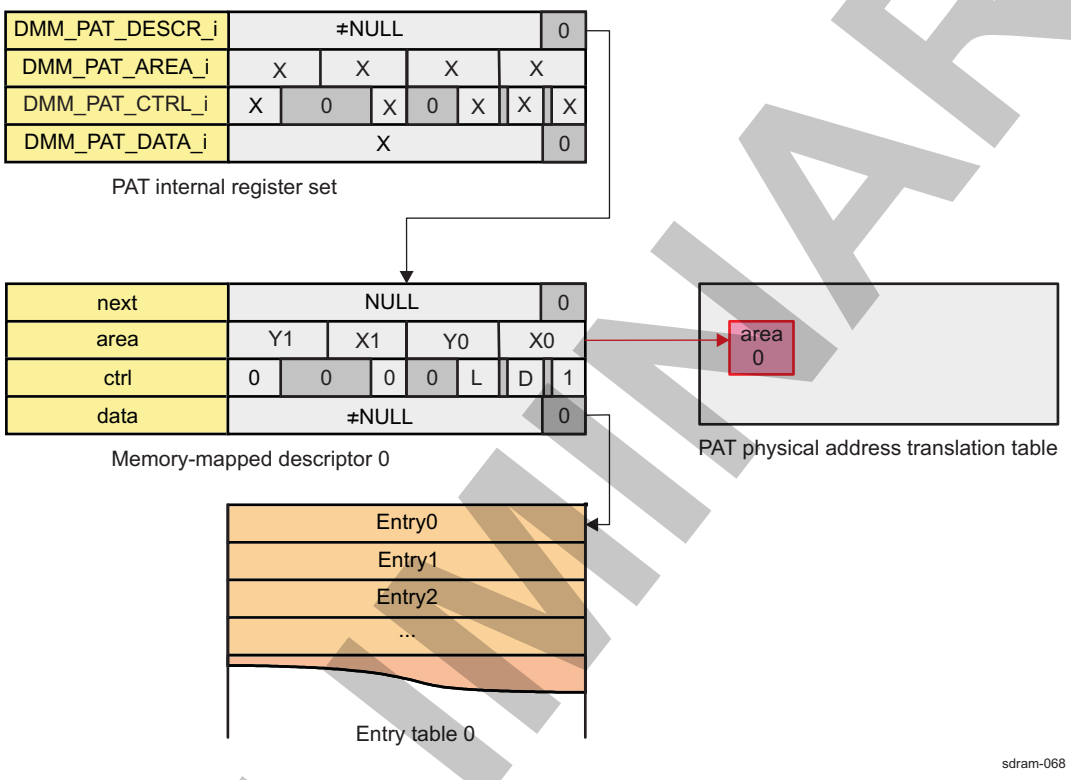
Copyright © 2013, Texas Instruments Incorporated

present in the system, and the START bit is asserted to start refilling as soon as this descriptor enters the PAT refill engine.

- The data field is set to the physical address of the created entry table.

2. Write the DMM_PAT_DESCR_i register with the physical address of the created descriptor.
3. The refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 15-38. Single Auto-Configured Area Refill Scheme



15.2.4.1.3 Chained Auto-Configured Area Refill

The following must be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-39):

1. Create one 16-byte aligned memory-mapped descriptor structure per area where:
   - The next field is set to the physical address of the next descriptor or NULL for the last one.
   - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
   - The ctrl field is set with the requested direction D, with the requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as the previous area refill is done.
   - The data field is set to the physical address of the corresponding entry table.
2. Write the DMM_PAT_DESCR_i register with the physical address of the first created descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. All area refills are done when the DMM_PAT_STATUS_i[0] READY bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

PRELIMINARY

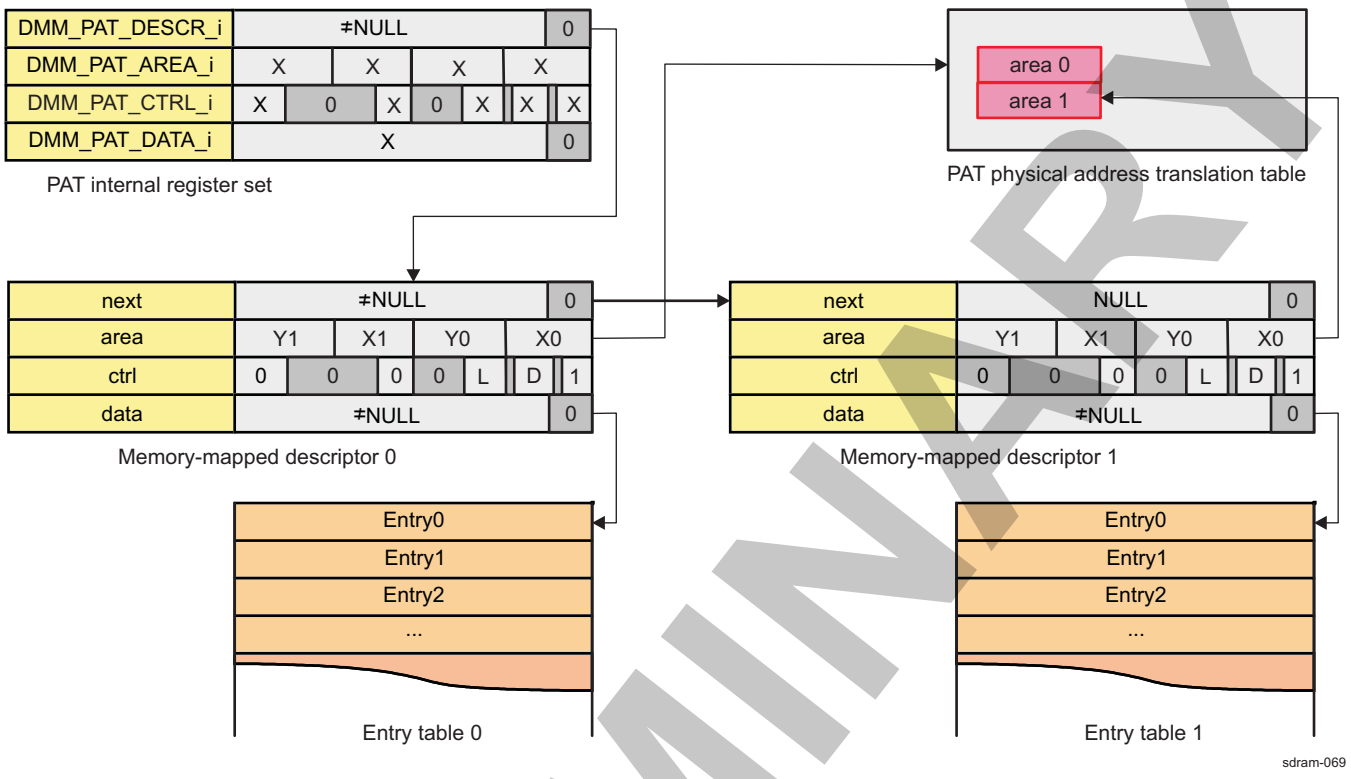
Figure 15-39. Chained Auto-Configured Area Refill Scheme



15.2.4.1.4 Synchronized Auto-Configured Area Refill

The following must be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-40):

1. Create one 16-byte aligned memory-mapped descriptor structure per area where:
   - The next field is set to the physical address of the next descriptor or NULL for the last one.
   - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
   - The ctrl field is set with the synchronizing initiator identifier I, the SYNC bit is asserted, the requested direction D and the requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area.
   - The data field is set to the physical address of the corresponding entry table.
2. Write the DMM_PAT_DESCR_i register with the physical address of the first created descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. All area refills are done when the DMM_PAT_STATUS_i[0] READY bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

PRELIMINARY

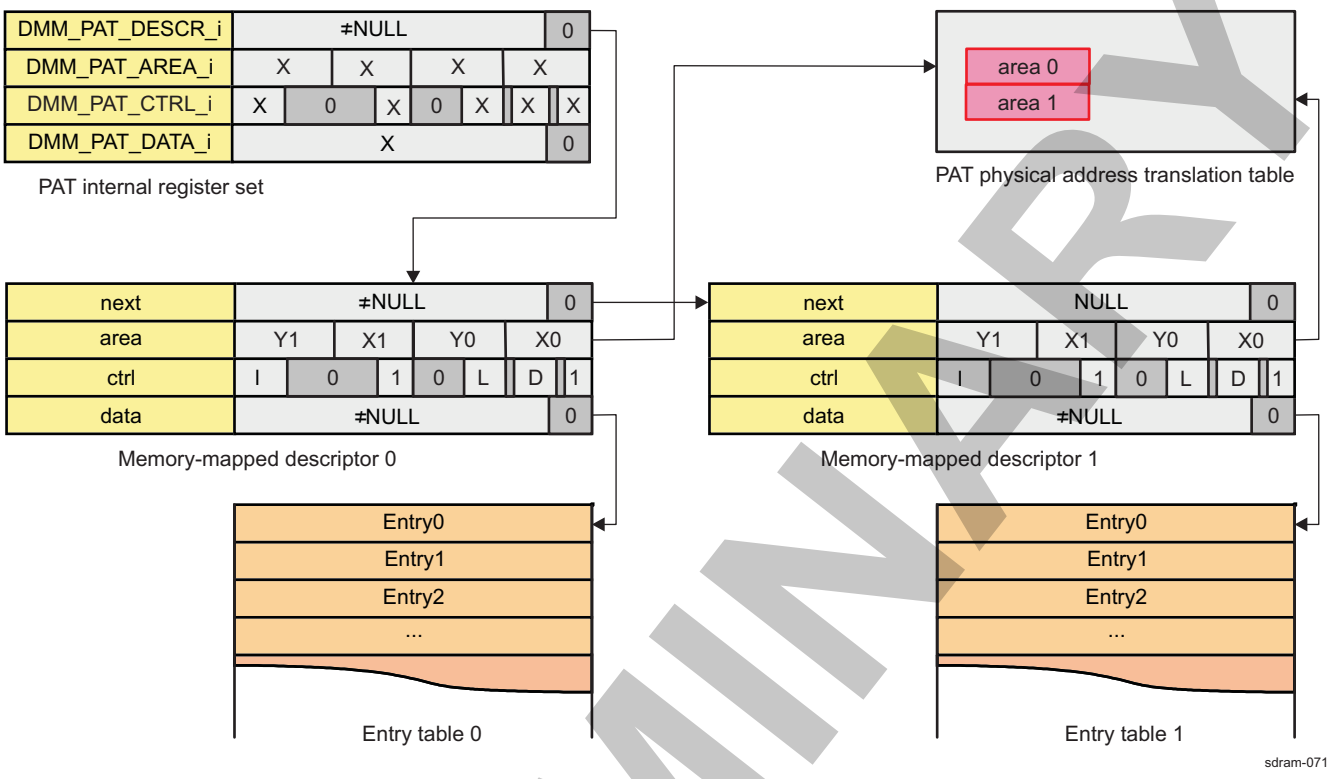
Figure 15-40. Synchronized Auto-Configured Area Refill Scheme



15.2.4.1.5 Cyclic Synchronized Auto-Configured Area Refill

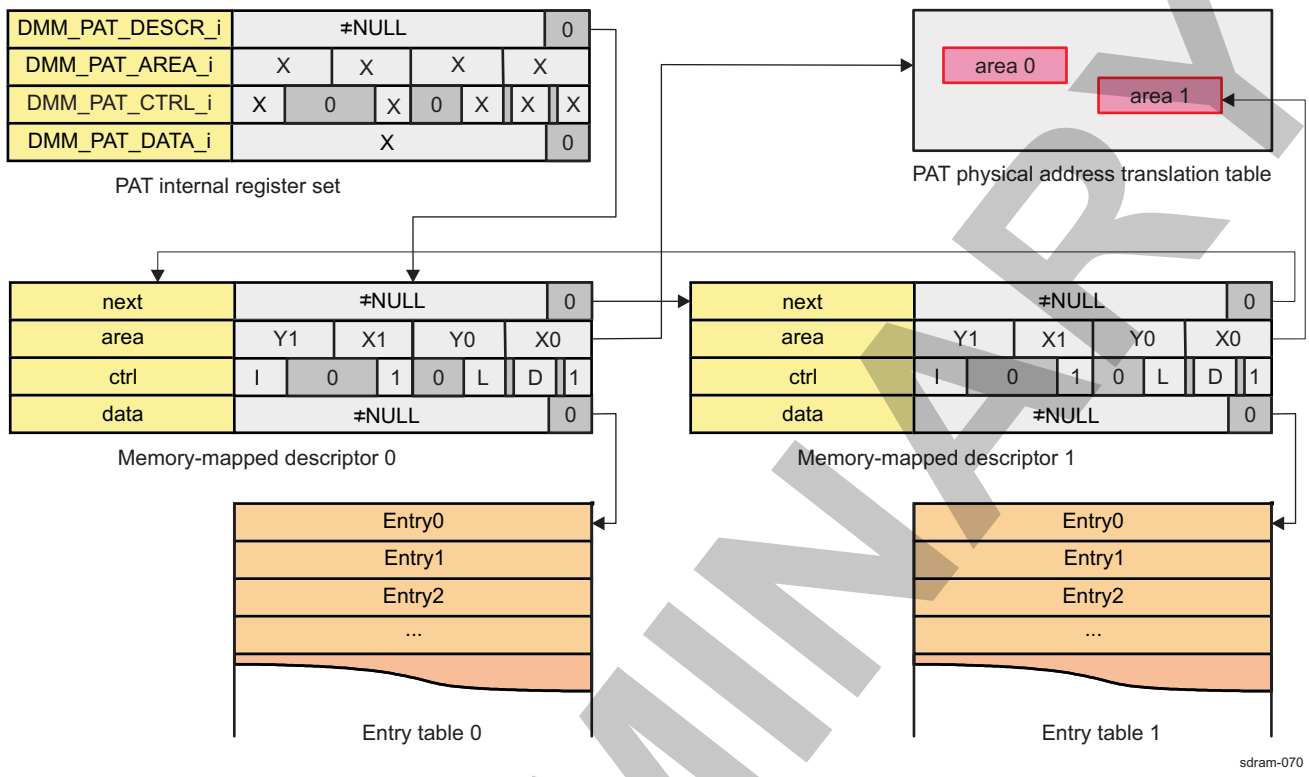
The following must be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-41):

1. Create one 16-byte aligned memory-mapped descriptor structure per area where:
   - The next field is set to the physical address of the next descriptor in the circular list.
   - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
   - The ctrl field is set with the synchronizing initiator identifier I, the SYNC bit asserted, the requested direction D and requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area.
   - The data field is set to the physical address of the corresponding entry table.
2. Write the DMM_PAT_DESCR_i register with the physical address of the initial descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. A new refill can be initiated by writing any value to the DMM_PAT_DESCR_i register to abort the current one.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 15-41. Cyclic Synchronized Auto-Configured Area Refill Scheme



NOTE: Never use circular lists of descriptors where all descriptors have the DMM_PAT_CTRL_i[0] START bit set and there is no synchronization. This leads to an endless continuous refill.

15.2.4.2 Addressing Management with LISA

15.2.4.2.1 Case 1: Use of One Memory Controller

In this example, assume there is 1 GiB of external memory evenly spread onto two address spaces. The address range for address space 0 must start at offset 0x2000_0000 (see Table 15-20).

Table 15-20. Address Definition

Address Range	Memory Controller	Memory Controller Address Space[(1)]	Memory Controller Address Range
0x8000_0000 to 0x9FFF_FFFF	EMIF1	0x1	0x0000_0000 to 0x1FFF_FFFF
0xA000_0000 to 0xBFFF_FFFF	EMIF1	0x0	0x2000_0000 to 0x3FFF_FFFF

(1) For memory controller address spaces, see , *Local Interface*.

This configuration requires two nonoverlapping sections to be set. They can be defined in any order because there is no concern with priority in this case (see Table 15-21):

Table 15-21. Configuration

Bit Field	Section 0 (DMM_LISA_MAP_0)	Section 1 (DMM_LISA_MAP_1)
[31:24] SYS_ADDR	0x80	0xA0
[22:20] SYS_SIZE	0x5	0x5
[19:18] SDRC_INTL	0x0 (not applicable)	0x0 (not applicable)

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

Table 15-21. Configuration (continued)

Bit Field	Section 0 (DMM_LISA_MAP_0)	Section 1 (DMM_LISA_MAP_1)
[17:16] SDRC_ADDRSPC	0x1	0x0
[9:8] SDRC_MAP	0x1 (only EMIF1)	0x1 (only EMIF1)
[7:0] SDRC_ADDR	0x00	0x20

To check whether an address hits a section, use the 8 upper address bits of the address and mask them with the hit mask: 2^8–2^{SYS_SIZE}. If the result is equal to SYS_ADDR, the section is hit.

To define the physical address to be issued to the memory controller, use the 8 upper address bits of the system address, mask them with the address mask: 2^{SYS_SIZE}–1, and OR them with SDRC_ADDR. This gives the resulting 8 upper physical address bits. All lower address bits are forwarded unchanged.

Request to address 0x99AE_37F0:

- Upper address bits: 0x99
- Hit mask: 2^8–2^5 = 0xE0
- Masked upper address bits: 0x80, that is, hits section 0
- Address mask: 2^5–1 = 0x1F
- Masked upper address bits: 0x19
- OR with SDRC_ADDR: 0x19
- Physical address: 0x19AE_37F0

This request is forwarded to address 0x19AE_37F0, address space 1 of the memory controller.

Request to address 0xB7FF_0340:

- Upper address bits: 0xB7
- Hit mask: 2^8–2^5 = 0xE0
- Masked upper address bits: 0xA0, that is, hits section 1
- Address mask: 2^5–1 = 0x1F
- Masked upper address bits: 0x17
- OR with SDRC_ADDR: 0x37
- Physical address: 0x37FF_0340

This request is forwarded to address 0x37FF_0340, address space 0 of the memory controller.

15.2.4.2.2 Case 2: Use of Two Memory Controllers

In the case of 512 MiB interleaved at 128-byte boundaries and 256 MiB noninterleaved on the second memory controller, one address space per memory controller, we have the following results (see Table 15-22).

Table 15-22. Address Definition

Address Range	Memory Controller	Memory Controller Address Space[(1)]	Memory Controller Address Range
0x8000_0000 to 0x9FFF_FFFF	EMIF1 and EMIF2, interleaved at 128-byte boundaries	0x0 on both controllers	0x0000_0000 to 0x0FFF_FFFF on both controllers
0xA000_0000 to 0xAFFF_FFFF	EMIF2 only	0x0	0x1000_0000 to 0x1FFF_FFFF

(1) For memory controller address spaces, see , *Local Interface*.

Two sections are used to map such a configuration (see Table 15-23).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 15-23. Configuration

Bit Field	Section 0 (DMM_LISA_MAP_0)	Section 1 (DMM_LISA_MAP_1)
[31:24] SYS_ADDR	0x80	0xA0
[22:20] SYS_SIZE	0x5	0x4
[19:18] SDRC_INTL	0x1	0x0 (not applicable)
[17:16] SDRC_ADDRSPC	0x0	0x0
[9:8] SDRC_MAP	0x3	0x2
[7:0] SDRC_ADDR	0x00	0x10

Detecting a section hit is the same for the interleaved case as for the single controller case: To check whether an address hits a section, use the 8 upper address bits of the address and mask them with the hit mask: 28–2^{SYS_SIZE}. If the result is equal to SYS_ADDR, the section is hit.

The physical address generation is modified for the interleaved case. In case of 256-byte interleaving, the first chunk of 256 bytes is mapped to the first controller, the second chunk to the second controller, and so on. This results in system address bit 8 to be decoded as the controller indicator, 0 for the first controller, and 1 for the second controller (system address bit 7 is used for interleaving at the 128-byte boundary, and bit 9 for 512 bytes). This bit is not included in the computed physical address, meaning the upper system address bits [31:9] are shifted to bits [30:8] when generating the physical address.

The rest of the address generation is handled the same as for the single controller case: to define the physical address to be issued to the memory controller, use the 8 upper address bits of the system address, mask them with the address mask: 2^{SYS_SIZE}–1, and OR them with SDRC_ADDR. This gives the resulting 8 upper physical address bits. All lower address bits are forwarded unchanged.

Request to address 0x99AE_37F0:

- Upper address bits: 0x99
- Hit mask: 2^8–2^5 = 0xE0
- Masked upper address bits: 0x80, that is, hits section 0
- Address mask: 2^5–1 = 0x1F
- Masked upper address bits: 0x19
- Full masked address: 0x19AE_37F0
- Bit 7 is 1, that is, targets the second memory controller
- Full masked shifted address (suppressing bit 7): 0x0CD7_1BF0 (see Section 15.2.4.2.2.1)
- OR upper physical address bits with SDRC_ADDR: 0x0CD7_1BF0
- Physical address: 0x0CD7_1BF0

This request is forwarded to address 0x0CD7_1BF0, address space 0, of the second memory controller.

15.2.5 DMM Basic Programming Model

The programming model section:

- Describes how objects can be addressed in all TILER modes and orientations
- Explains how the physical containers and PAT LUT can be shared between different modes
- Does not give an exhaustive description of the TILER and DMM registers, because these are described in Section 15.2.3.5, *DMM*, and Section 15.2.3.6, *TILER*.

15.2.5.1 Global Initialization

This section identifies the requirements for initializing the surrounding modules when the DMM is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DMM (see Table 15-25).

Table 15-25. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. See Section 3.1.1, *Power, Reset, and Clock Management.*
Image processing unit (IPU)	IPU interrupt controller (INTC) configuration must be done to enable the interrupts from the DMM. See Section 17.1, *Interrupt Controllers.*
Main processing unit (MPU)	MPU INTC configuration must be done to enable interrupts from the DMM. See Section 17.1, *Interrupt Controllers.*
L3_MAIN interconnect	Data interface

15.2.5.2 DMM Module Global Initialization

Theprocedure in Table 15-26 initializes the DMM after a power-on reset (POR).

Table 15-26. DMM Global Initialization

Step	Register/Bit Field/Programming Model	Value
Configure the DMM for smart-idle power management mode.	DMM_SYSCONFIG[3:2] IDLE_MODE	0x2

15.2.5.3 DMM Operational Modes Configuration

15.2.5.3.1 Different Operational Modes

The TILER can be virtually accessed in four different modes: 8-, 16-, 32-bit, and page modes. Each mode defines the element granularity to apply isometric transforms (see Table 15-27).

Table 15-27. Coding and Description of TILER Modes

Mode	Name	Granularity (Element Size)
0	8-bit tiled mode	8 bits
1	16-bit tiled mode	16 bits
2	32-bit tiled mode	32 bits
3	Page mode	4096 bytes

15.2.5.3.2 Configuration Settings and LUT Refill

The procedure in Table 15-28 provides the configuration settings and LUT refill.

PRELIMINARY

15.2.5.3.5 Priority Settings

The procedure in Table 15-31 provides the sequence to set priorities.

Table 15-31. Priority Settings

Step	Register/Bit Field/Programming Model	Value
Set priority for each initiator.	DMM_PEG_PRIO_k Px	xxx
Set write enable for P_PAT field.	DMM_PEG_PRIO_PAT[4] W_PAT	xxx
Set priority for PAT engine.	DMM_PEG_PRIO_PAT[2:0] W_PAT	xxx

15.2.5.3.6 Error Handling

The procedure in Table 15-32 provides the sequence for error handling.

Table 15-32. Error Handling

Step	Register/Bit Field/Programming Model	Value
Enable interrupt for selected type of error.	DMM_PAT_IRQENABLE_SET[15:9] DMM_PAT_IRQENABLE_SET[7:0]	xxx
When interrupt occurs		
Disable type of error to handle.	DMM_PAT_IRQENABLE_CLR[15:9] DMM_PAT_IRQENABLE_CLR[7:0]	xxx
Check error status.	DMM_PAT_IRQSTATUS[15:9] DMM_PAT_IRQSTATUS[7:0]	xxx

15.2.5.3.7 PAT Programming Model

The PAT maps the tiled data anywhere in the 4-GiB physical address range, with a PAGE granularity. (The TILER page is the granularity of physical memory allocation in the TILER container. Each page is 4kiB).

A PAT view defines the kind of PAT to perform for each page, 8-, 16-, and 32-bit mode access. Each mode in each PAT view can be programmed in two different modes: direct translation and indirect translation.

15.2.5.3.7.1 PAT in Direct Translation Mode

In this mode, the PAT performs a translation of the 128-MiB virtual container as a whole in the physical address space (that is, in the SDRAM). This mode is used only for debug or in case of a DMM without a PAT.

15.2.5.3.7.2 PAT in Indirect Translation Mode

This is the most commonly used mode. In this mode, the PAT performs a translation of each 4-KiB page individually. In this way the 128-MiB virtual address space can be scattered in the whole 2 GiB of the physical address space. This is achieved by using a 32,678-word LUT that converts each page index (32,768 possible values) into 19 address bits that represent this page address in the physical memory. The main characteristic of this mode is there is no constraint on the use of the physical memory except that it is uses a multiple of 4-KiB areas located at 4-KiB boundaries in the physical memory. In this mode, the translation vector is in the internal 32-k entry PAT vector table at the index given by bits [26:12] of the input virtual address, and CONT_x = 0.

Programming sequence:

1. Set the DMM_PAT_VIEW0 register (or DMM_PAT_VIEW1, depending on the L3 CONN_ID of the initiator that is to perform the tiled accesses) with the appropriate value. For example, if the L3 CONN_ID equals 0, then the DMM_PAT_VIEW0 register must be programmed with the value 0x0000_0001 (PAT view 1 selected for initiator 0).
2. Set DMM_PAT_VIEW_MAP_BASE[31] = 0x8000_0000 (must always be programmed at 1 to select the upper 2 GiB of the physical address space that corresponds to the external memory).

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

3. Set all 16-bit tiled accesses in indirect translation mode by setting at least the field ACCESS_16 to 1 (DMM_PAT_VIEW_MAP_1 = 0x0000_8000), program DMM_PAT_VIEW_MAP_1 at 0x8080_8080.

15.2.5.4 Addressing an Object in Tiled Mode

This section describes how a frame-buffer with a top-left pixel at (x0,y0) in the natural view container and a bottom right pixel at (x1,y1) in the natural view container is addressed in any tiled mode and orientation.

15.2.5.4.1 Frame-Buffer Addressing

NOTE: In this section, the (x,y) coordinates are given in pixel units.

Given an (S, $\overline{Y}$, $\overline{X}$) orientation, the (x,y) coordinates of the first pixel of the frame in the oriented view (where W = the width and H = the height in pixels of the container in the considered frame mode) is:

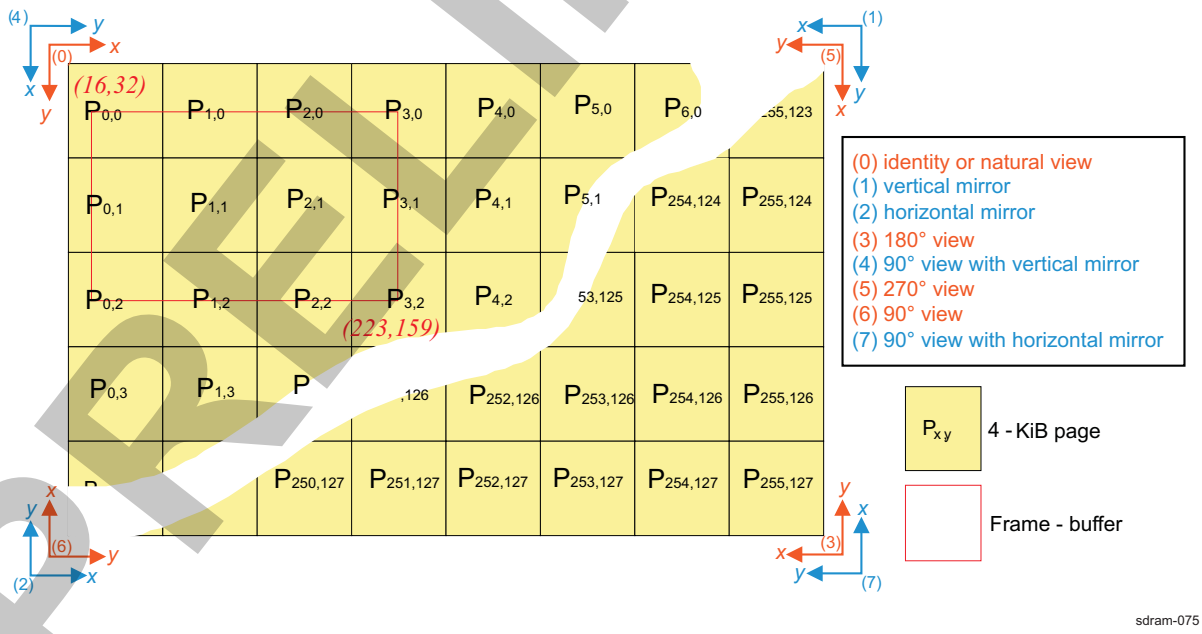
(x,y) = (x_{or}, y_{or}) when S, (y_{or}, x_{or}) otherwise
with:
x_{or} = x_0 when $\overline{X}$, W-1-x_1 otherwise
y_{or} = y_0 when $\overline{Y}$, H-1-y_1 otherwise

Given a (M_1, M_0) TILER mode where M_1 # 0 or M_0 # 0, the size in bytes of a pixel is 2^{2M1+M0}.

Therefore, given an (S, $\overline{Y}$, $\overline{X}$) orientation and a n(M_1, M_0) TILER mode where M_1 # 0 or M_0 # 0, the byte offset of the base address of the considered oriented frame in its container is:
base_address((x_0, y_0), (x_1, y_1), (S, $\overline{Y}$, $\overline{X}$), (M_1, M_0)) = (y_{or}W + x_{or}) P_5 when S, (x_{or}H + y_{or}) P_5 otherwise
with:
x_{or} = x_0 when $\overline{X}$, W-1-x_1 otherwise
y_{or} = y_0 when $\overline{Y}$, H-1-y_1 otherwise
P_5 = 2^{2M1+M0}

In its natural orientation, the TILER container consists of 8192 lines of 16,384 pixels of 8 bits, or 4096 lines of 16,384 pixels of 16 bits, or 4096 lines of 8192 pixels of 32 bits.

Figure 15-42. Example of 8-Bit Frame-Buffer Addressing in any Orientation



This frame-buffer address generation is independent from the page size. For instance, the 8-bit frame-buffer shown in Figure 15-42 that ranges from the top-left pixel at (16, 32) to the bottom-right pixel at (223, 159) in the natural orientation view, corresponds to the 29-bit view address offsets and full 33-bit TILER addresses given in Table 15-33.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

Table 15-33. 29-Bit View Address Offset and 33-Bit Full TILER Address for an 8-Bit Frame-Buffer

S	$\overline{Y}$	$\overline{X}$	x_{or}	y_{or}	29-Bit Address Offset in View	Full 33-Bit TILER Address
0	0	0	16	32	00080010h	100080010h
0	0	1	16,160	32	00083F20h	120083F20h
0	1	0	16	8032	07D80010h	147D80010h
0	1	1	16,160	8032	07D83F20h	167D83F20h
1	0	0	16	32	00020020h	180020020h
1	0	1	16,160	32	07E40020h	1A7E40020h
1	1	0	16	8032	00021F60h	1C0021F60h
1	1	1	16,160	8032	07E41F60h	1E7E41F60h

In this example the TILER is addressed in 8-bit mode, which translates to addresses with all mode bits (bits 27 and 28) cleared in the 29-bit address offset in view and in the full 33-bit TILER address.

15.2.5.4.2 TILER Page Mapping

Let:

- c (c = 0, 1, or 2) be the TILER page configuration (0 for 4-kiB pages, 1 for 16-kiB pages, and 2 for 64-kiB pages)
- (x_0, y_0) be the top-left pixel and (x_1, y_1) be the bottom-right pixel of a frame in its natural orientation
- W be the width and H the height in pixels of the container in the considered frame mode

The top-left page coordinates (P_{x0}, P_{y0}) and bottom-right page coordinates (P_{x1}, P_{y1}) that correspond to the frame are given by: $P_{x0} = (64.x_0.2^{2-c}) / W$, $P_{y0} = (32.y_0.2^{2-c}) / H$, $P_{x1} = (64.x_1.2^{2-c}) / W$ and $P_{y1} = (32.y_1.2^{2-c}) / H$.

In its natural orientation, the TILER container consists of 8192 lines of 16,384 pixels of 8 bits, or 4096 lines of 16,384 pixels of 16 bits, or 4096 lines of 8192 pixels of 32 bits.

NOTE: The page area type has the same structure as the DMM_PAT_AREA_i registers. For instance, the 8-bit frame-buffer described in Figure 15-42 and ranging from the top-left pixel at (16, 32) to the bottom-right pixel at (223, 159) in the natural orientation view, is mapped from the top-left page at P0,0 to the bottom-right page P3,2.

15.2.5.5 Addressing an Object in Page Mode

In page mode, the orientation modifies only the sequence of accessed pages, not their content. In this respect the orientation must be seen as a way to optimize the one-dimensional (1D) object allocation in a TILER container by allowing a 1D object spanning multiple pages to map a set of adjacent pages in any direction. For instance, a 1.25-MiB object, mapped on 320 pages of 4kiB can be allocated in a TILER container in any of the eight orientations (see Section 15.2.3.6.1.7.3, *Element Ordering in the TILER Container*).

The initial page can be chosen freely among all pages. In this respect, the address offset of a page in a TILER container is expressed as:

Let:

- c (c = 0, 1 or 2) be the TILER page configuration (0 for 4-kiB pages, 1 for 16-kiB pages, and 2 for 64-kiB pages)
- $(S, \overline{Y}, \overline{X})$ be the orientation of the considered 1D object in page mode
- (P_x, P_y) be the coordinate of the initial page in the natural orientation view

The byte offset of the base address of the considered initial page in its oriented container is:
$base_address((P_x, P_y), (S, \overline{Y}, \overline{X})) = 4096.(64.y_{or}.2^{2-c} + x_{or}).2^{2.c}$ when S, $4096.(32.x_{or}.2^{2-c} + y_{or}).2^{2.c}$ otherwise with:
$x_{or} = P_x$ when $\overline{X}$, $64.2^{2-c}\text{-}1\text{-}P_x$ otherwise
$y_{or} = P_y$ when $\overline{Y}$, $32.2^{2-c}\text{-}1\text{-}P_y$ otherwise

Copyright © 2013, Texas Instruments Incorporated

For instance, a 1D object starting from the page P32,63 in the natural orientation view on a DMM using 4-kiB pages, corresponds to the 29-bit view address offsets and full 33-bit TILER addresses given in Table 15-34.

Table 15-34. 29-Bit View Address Offset and 33-Bit Full TILER Address for a 1D Object

S	$\overline{Y}$	$\overline{X}$	x_{or}	y_{or}	29-Bit Address Offset in View	Full 33-Bit TILER Address
0	0	0	32	63	1BF20000h	11BF20000h
0	0	1	223	63	1BFDF000h	13BFDF000h
0	1	0	32	64	1C020000h	15C020000h
0	1	1	223	64	1C0DF000h	17C0DF000h
1	0	0	32	63	1903F000h	19903F000h
1	0	1	223	63	1EFBF000h	1BEFBF000h
1	1	0	32	64	19040000h	1D9040000h
1	1	1	223	64	1EFC0000h	1FEFC0000h

In this example the TILER is addressed in page mode, which translates to addresses with mode bits (bits 27 and 28) set in the 29-bit address offset in view and full 33-bit TILER address.

15.2.5.6 Sharing Containers Between Different Modes

When allocating objects in TILER containers, ensure that no two objects physically overlap.

In this respect, and to ease the object allocation and deallocation, it is strongly advised to share a TILER page only for different objects that do both of the following:

- Belong to the same mode
- Have the same lifetime (that is, are allocated and deallocated simultaneously)

Two objects of different modes can physically overlap if:

- One physical page is mapped twice in two different locations of the DMM LUT.
- The two objects share the DMM LUT and the intersection of their two page set is not empty.

  These two issues can be easily avoided by allocating a physical page only once in the DMM LUT.

  The second issue is a bit more difficult, especially if the allocation of objects in the various TILER containers must be dynamic. Managing the fragmentation within a flat memory model in a space-constrained system is not straightforward, and is the main reason for the existence of MMUs in most current processors, which adds yet another constraint to the problem (the y dimension, which makes it even more difficult).

Returning to the CPU-analogy, the memory fragmentation issue is mostly solved by using a virtual memory space larger than the actual physical memory space and a virtual-to-physical translation system. This allows contiguous virtual memory allocation when sufficient physical memory is available and the larger contiguous physical buffer is smaller than the requested memory allocation.

Similarly, the DMM answer to this object allocation in the TILER containers is two-fold:

- The DMM must have sufficient virtual address space in all modes to permit a static allocation of a pool of virtual buffers in all TILER modes for all TILER-aware initiators.
- Each TILER-aware initiator must dynamically manage its own pool of virtual buffers.

Table 15-73. DMM_PAT_IRQSTATUS

Address Offset	0x0000 0490		
Physical Address	0x4E00 0490	**Instance**	DMM
Description	Per-event "enabled" interrupt status vector. Enabled status is not set unless the event is enabled. Write 1 to clear the status after interrupt has been serviced (raw status gets cleared, that is, even if not enabled). n = 0 for the first interrupt status register, n = 1 for the second interrupt status register.		
Type	RW

15.3 EMIF Controller

This section describes the features and functions of the external memory interface (EMIF) module of the device.

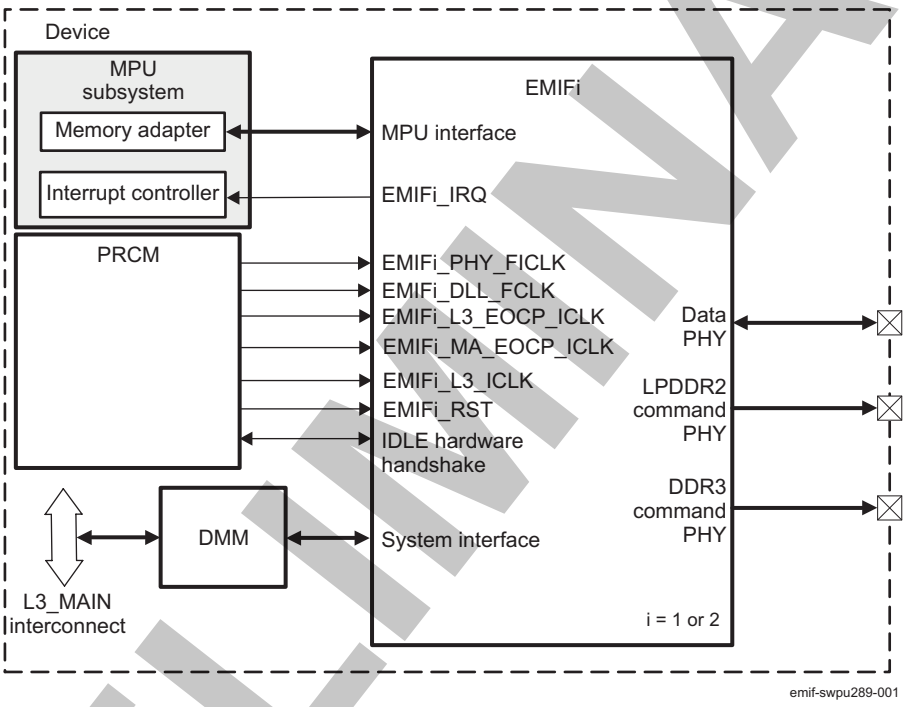
15.3.1 EMIF Module Overview

The EMIF module provides connectivity between the device and LPDDR2-type or DDR3-type of memories and manages data bus read/write accesses between external memories and the device subsystems having access to the L3_MAIN interconnect and DMA capability.

The EMIF is also introduced in Section 15.1, *Memory Subsystem Overview*.

The device includes two EMIF controllers. Figure 15-43 is an overview of the EMIF modules.

Figure 15-43. EMIF Module Overview



15.3.1.1 EMIF Overall Integration

Figure 15-44 shows the EMIF connection with the surrounding modules and SDRAM devices.

15.3.4 EMIF Functional Description

15.3.4.1 Block Diagram

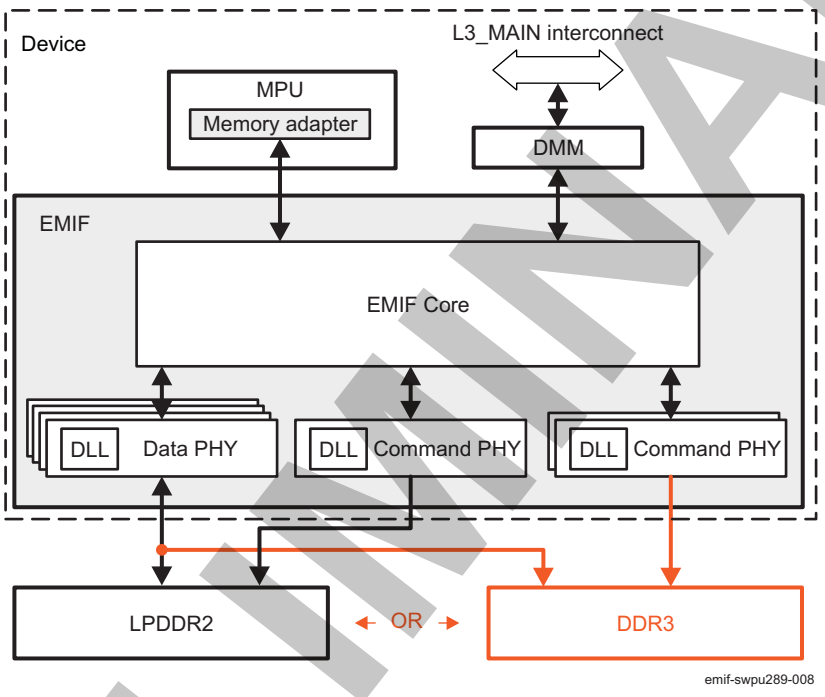
The EMIF is an L3 bus peripheral that provides an interface to SDRAM memories.

Figure 15-49 shows the interconnection between the EMIF module and the other modules.

Digital locked loops (DLLs) are used to delay the input DQS signals during reads so that these strobe signals can be used to latch incoming data on the DQ pins, as required by the DDR standard.

Physical layers (PHYs) convert single-data rate (SDR) signals to DDR signals.

Figure 15-49. EMIF Block Diagram



15.3.4.1.1 Local Interface

The EMIF supports three local (on-chip) interfaces:

- System interface (from L3_MAIN interconnect)
- MPU interface (from MPU subsystem)
- Low-latency interface This interface is not connected to any subsystem in this device.

System and Low-latency interfaces are used to request all external memory device accesses, to access the EMIF registers, and to transfer all data to and from the EMIF controller. MPU interface is used to process memory accesses. Each interface has its own clock.

Table 15-100 shows the MAddrSpace mapping to different CSs.

Table 15-100. MAddrSpace Mapping to Chip-Selects

MAddrSpace[1]	Chip-Select	Description	Exclusions
0x0	NCS[1:0]	SDRAM(s)	
0x1	NCS1	Reserved for LPDDR2-NVM	Not supported
0x2	N/A	Reserved. Any access to this area will generate an error on the L3 interface. This can be used by the software to track any unwanted access to the section defined in the DMM_LISA_MAP_i register.	Not visible to the MPU port

(1) See DMM_LISA_MAP_i [17:16] SDRC_ADDRSPC register bitfield in Section 15.2, *Dynamic Memory Manager*.

Table 15-100. MAddrSpace Mapping to Chip-Selects (continued)

MAddrSpace[1]	Chip-Select	Description	Exclusions
0x3	N/A	Internal registers	Not visible to the MPU port

Table 15-101 lists the features of the EMIF interface port.

Table 15-101. Port Features

Feature	System	LL (not connected)	MPU
64-bit bus		√	
128-bit bus	√		√
Register access	√	√	
2D access	√	√	

15.3.4.1.2 FIFO Description

The EMIF module contains the following FIFOs:

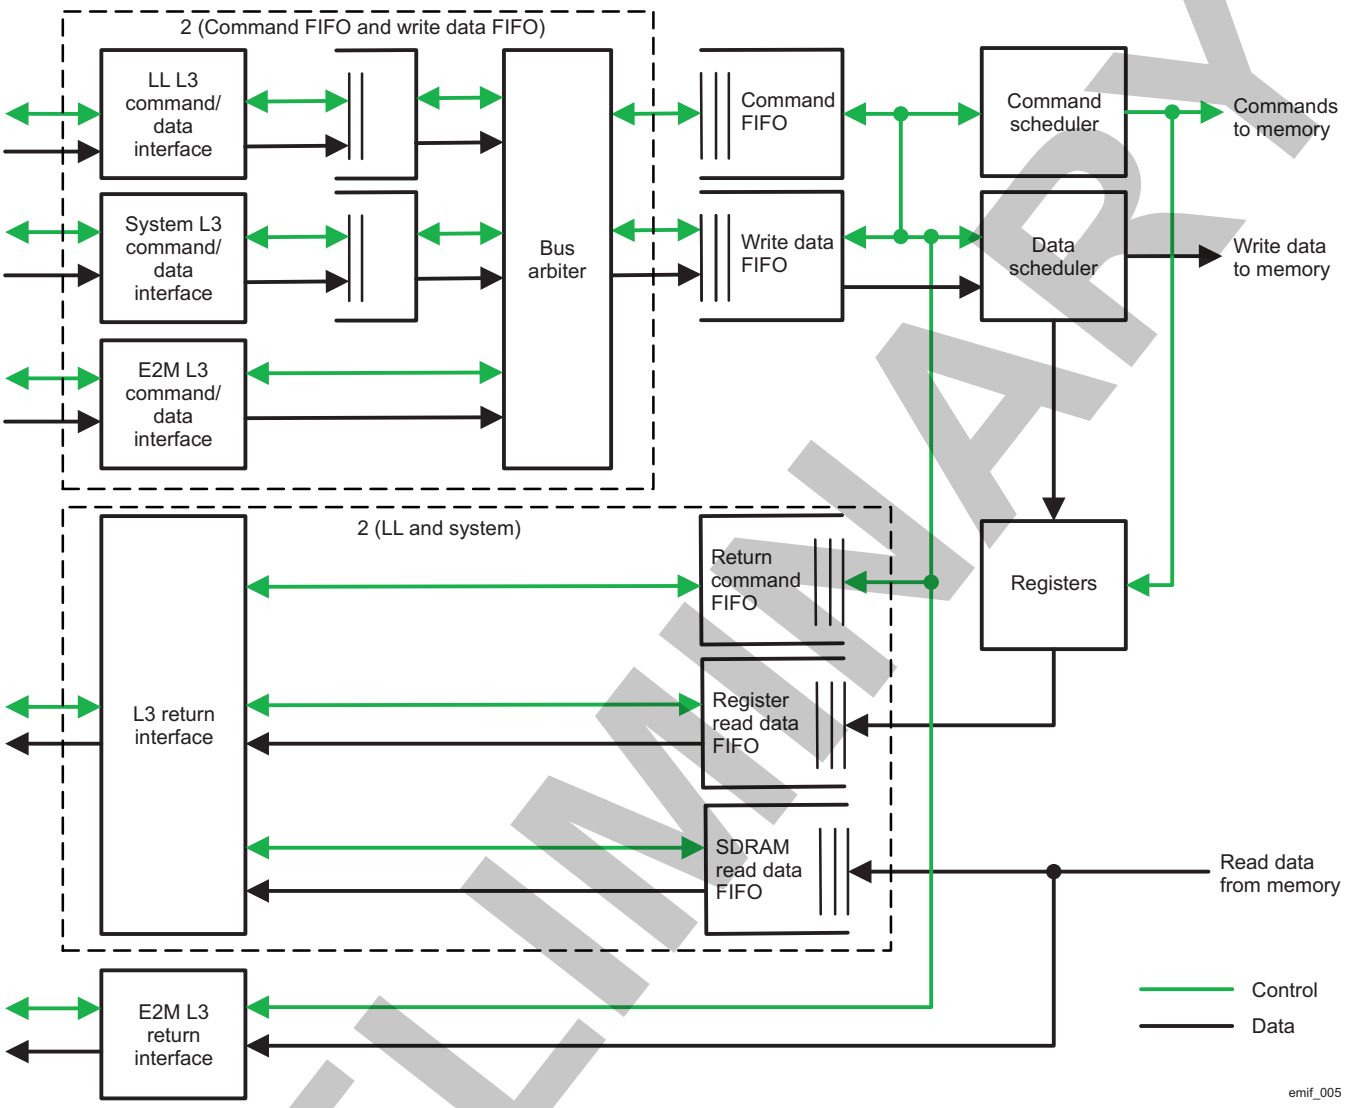
- Command FIFO
- Write data FIFO
- Return command FIFO
- Two read data FIFOs

Figure 15-50 shows the overall architecture of the EMIF FIFOs.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 15-50. FIFO Block Diagram



Because the system (128-bit) local interface is the main interface, it has a higher allocation of FIFO slots than the low-latency (64-bit) local interface. Table 15-102 lists the allocation of the entries.

Table 15-102. FIFO Allocation

Parameter	System Local Interface Entries	Low-Latency Local Interface Entries	MPU Local Interface Entries
Pre Command FIFO	6	6	4
Command FIFO	Programmable (1)	Programmable (1)	Programmable (1)
Pre Write FIFO	6	6	8
Write Data FIFO (256-bit)	Up to (19 × 256 bits) + 6	Up to (19 × 256 bits) + 6	Up to 19 + 8
Return Command FIFO	22	17	24
SDRAM Read Data FIFO	22	17	24
Register Read Data FIFO	2	2	0

(1) The total number of entries in the command FIFO is 10.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The command FIFO is shared between the three local interfaces, whereas there are three different FIFOs for every other type, one dedicated to each local interface.

The command FIFO stores all the commands coming in on the local command interface. The allocation of entries in the command FIFO is programmable per local interface using the following bit fields:

- EMIF_OCP_CONFIG[27:24] SYS_THRESH_MAX
- EMIF_OCP_CONFIG[19:16] LL_THRESH_MAX
- EMIF_OCP_CONFIG[23:20] MPU_TRESH_MAX

If the addition of the EMIF_OCP_CONFIG[27:24] SYS_THRESH_MAX and EMIF_OCP_CONFIG[19:16] LL_THRESH_MAX bit fields is greater than the number of entries in the command FIFO, the allocation depends on the traffic on the interfaces. For example, if both fields are programmed to 7, then either of the interfaces can use seven entries in the command FIFO if the other interface is idle. If both interfaces have traffic, then the EMIF starts to gradually allocate entries to both interfaces until it settles down to seven entries for the low-latency interface and three entries for the system interface, because the low-latency interface has higher priority. If the low-latency interface has no traffic, the system interface can use seven entries.

The allocation also depends on the traffic on the interfaces, if the EMIF_OCP_CONFIG[27:24] SYS_THRESH_MAX and EMIF_OCP_CONFIG[19:16] LL_THRESH_MAX bit fields are programmed to be equal to or greater than the number of entries in the command FIFO. For example, if both fields are programmed to 10, then the low-latency port can use all the entries if there is no traffic on the system interface. However, if there is no traffic on the low-latency interface, the system interface can use all but one entry. This is because the low-latency interface has higher priority than the system interface. The only way for the system interface to use all command FIFO entries is to set the EMIF_OCP_CONFIG[19:16] LL_THRESH_MAX bit field to 0. Writing 0 reserves no space for the associated interface. If the value is set to 0 and a request is seen for that interface, the command FIFO assumes a value of 1 for that interface.

The write data FIFO stores the write data for all the write transactions coming in on the local write data interface. The write FIFO is shared for all the ports. A similar token mechanism is used to allocate the write FIFO with the following exceptions. All ports are given a minimum of four tokens, which ensures that each has ensured access to three write FIFO locations. Any one port can only use up to 19 of the 25 write FIFO locations. Because there is a 6-word pre-FIFO, each port can have up to 25 backlogged writes. The LL interface can have up to twice the logged write data values, because the interface is 50 percent of the internal data storage.

The return command FIFO stores all the return transactions that are to be issued to the local return interface. These include the write status return and the read data return commands.

Two read data FIFOs store the read data to be sent to the local return interface. One read data FIFO stores read data from the memory mapped registers. The other read data FIFO stores read data from external memory.

A write command is executed only when four local words of the corresponding data is received in the write data FIFO, or when it is the last data, and if there is space in the return command FIFO. The EMIF schedules a read-only if the results can fit into the return command FIFO and the corresponding read data FIFOs.

15.3.4.1.3 MPU Port Restrictions

The EMIF MPU port is defined only to process memory requests. All register accesses are processed through the system or LL ports of the EMIF. The EMIF MPU port does not support 2D or register requests required or provided by the system and LL interfaces.

15.3.4.1.4 Port Priority

When Mflag = 0, or when the Mflag port override bit (EMIF_READ_WRITE_EXECUTION_THRESHOLD [31] MFLAG_OVERRIDE) is set:

1. LL port (highest priority)
2. System or MPU depending on the MPriority field of the MReqInfo bus

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

When Mflag = 1:

- The system port is given highest priority: EMIF guarantees one System command will be executed, before switching back to legacy priority scheme (above). This ping-pong arbitration scheme continues until Mflag is returned to 0.
- If no system command is present, the legacy priority scheme is maintained.
- If refresh_must is asserted, then only one refresh is retried, to prevent refresh cycles taking away from bandwidth during this critical time.

15.3.4.1.5 Coherency

To maintain coherency, the following rules must be followed:

- Any command arriving on any interface (MPU, system, or LL) that matches an address in the command FIFO is executed after the command in the command FIFO
- The matching address is any address within a 2,000-address boundary
- On a 2-D transfer, the starting address is the compared address. The computed addresses of the 2-D transfer are not considered in address overlapping.
- Any command arriving within a 10-cycle window of another, from the different interfaces that do not match any address in the command FIFO, but may match command addresses arriving on a different interface, can be executed in any order.

15.3.4.1.6 Arbitration of Commands in the Command FIFO

The EMIF looks at all the commands stored in the command FIFO to schedule commands to the external memory. All commands with the same MConnID on a particular local interface complete in order. The EMIF does not ensure ordering between commands with different MConnIDs or between commands from two local interfaces. For more information about L3 interconnect terms (MConnID, MCMD, MADDR, etc.) see Section 14.2.1, *L3 Interconnect*.

However, the EMIF does maintain data coherency. Therefore, the EMIF blocks a command, regardless of priority or the local interface, if that command is to the same block address (2048 bytes) as an older command that is not complete. Thus, the EMIF may have one pending read or write for each MConnID. Among all pending reads, the EMIF selects all reads that have their corresponding SDRAM banks already open. Similarly, among all pending writes, the EMIF selects all writes that have their corresponding SDRAM banks already open. Accesses to memory mapped registers are treated as accesses that have open banks.

As a result of this reordering, the EMIF may now have several pending reads and writes that have their corresponding banks open. The EMIF then selects the highest priority read from pending reads, and the highest priority write from pending writes. Commands from the low-latency local interface have a higher priority over the commands from the system local interface. If two or more commands have the highest priority, the EMIF selects the oldest command. As a result, the EMIF may now have the next read and a write command. If the return command FIFO and the read data FIFO have space and the external bus conflict is resolved, the EMIF performs the final read command before the final write command. If the return command FIFO has space but the read data FIFO is full, the EMIF performs the final write command before the final read command. Resolution of external bus conflict means all the SDRAM command-to-command counters are satisfied and the read-to-write or write-to-read turnaround time is met.

The EMIF does not support tag interleaving. In other words, for an local interface, the EMIF completes executing an local command before it switches to another command. The EMIF can, however, interleave execution between commands from two local interfaces.

The data coherency inside the EMIF is ensured only in a single level of local infrastructure. For example, if a write from a secondary local bus segment is blocked by a bridge element, the read from a tertiary bus can still beat the write to the EMIF. In such a case, to confirm that a write from master A has landed before a read from master B is performed, master A must wait for the write status from the EMIF before indicating to master B that the data is ready to be read. If master A does not use the local wait status, it must do the following:

1. Perform the required write.
2. Perform a dummy write to the EMIF_REVISION register.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

3. Perform a dummy read to the EMIF_REVISION register.
4. Indicate to master B that the data is ready to be read after completion of read in Step 3. The completion of read in Step 3 ensures that the previous writes were done.

Apart from reads and writes, the EMIF must also open and close SDRAM banks and maintain the refresh counts for an SDRAM. The priority of SDRAM commands with respect to refresh levels are:

1. SDRAM refresh request when refresh-must level is reached (highest priority)
2. ZQ calibration
3. Leveling
4. local request for a read or write
5. local request for a write
6. SDRAM activate commands
7. SDRAM deactivate commands
8. SDRAM deep power-down request
9. SDRAM power-down request
10. SDRAM refresh request when refresh-may or release level is reached
11. SDRAM self-refresh request (lowest priority)

While performing the previous scheduling algorithm, the EMIF may encounter two conditions:

- A continuous stream of high-priority commands can block lower priority commands.
- A continuous stream of SDRAM commands to a row in an open bank can block commands to another row in the same bank.

In addition to this scheduling, the highest priority condition is a reset command. If this condition occurs, the EMIF abandons what it is doing and begins its start-up sequence. In this case, commands and data stored in the FIFOs are lost. The EMIF also starts its start-up sequence whenever the EMIF_SDRAM_CONFIG register is written and the EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS bit is set to 0. In this case, commands and data stored in the FIFOs are not lost. The EMIF ensures that in-flight read or write transactions to the SDRAM are complete before starting the initialization sequence.

All the accesses to an SDRAM are pipelined to maximize use of the external bus. All of these are done while fulfilling the access timing requirements of an SDRAM.

15.3.4.2 Clock Management

The EMIF can gate EMIF_COREi. There is an internal mechanism that can stop EMIF_COREi automatically. EMIF_COREi is stopped only after the SDRAM is put into self-refresh mode and the power-idle protocol on the local bus completes. The EMIF_COREi frequency can be changed only after putting the external SDRAM in self-refresh mode.

The EMIF waits for the DLL lock before performing any memory access.

EMIF_COREi frequency is equal to half of the EMIFi_PHY_FICLK frequency.

15.3.4.3 Reset

The EMIF does not support a software reset.

The EMIF supports a global warm reset mode, during which the EMIF keeps the SDRAM content. Upon a request from the PRCM module indicating a need to enter global warm reset mode, the EMIF does the following:

1. During a leveling operation, EMIF will immediately exit the operation, and a load mode register access (DDR3) will be used to exit leveling mode. Also, the incremental leveling prescaler and count register values will be reset to zero, preventing incremental leveling from firing later and causing an undesired exit from self-refresh during a warm reset state.
2. EMIF completes the ongoing access, and then puts the SDRAM in self-refresh mode. If the EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS field is set to 1, the EMIF does not put SDRAM in self-refresh mode. If EMIF is in LPDDR2 mode and the

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

EMIF_LPDDR2_MODE_REG_CONFIG[30] REFRESH_EN is set to 0, the EMIF does not put LPDDR2 in self-refresh mode.

3. EMIF clears all its FIFO contents.
4. EMIF does not wait for all interrupts to be serviced.

To exit the global warm reset:

1. If the EMIF was in Self Refresh state, it will exit Self Refresh state.
2. If leveling was enabled at the time of a global warm reset, a PHY reset must occur to bring the PHY back into a known state, as it may have been left in a leveling state upon warm reset assertion. To guarantee the SDRAM memory clocks are off when issuing a PHY reset, the EMIF_POWER_MANAGEMENT_CONTROL register may be needed to enter self refresh before asserting PHY reset.
3. It is the responsibility of software to go through a full leveling and reinitialize any incremental leveling thereafter.

15.3.4.4 System Power Management

15.3.4.4.1 Power-Down Mode

The EMIF supports power-down mode for low power. The EMIF automatically puts the SDRAM into power-down mode after it is idle for EMIF_POWER_MANAGEMENT_CONTROL[15:12] PD_TIM number of DDR clock cycles and the EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is set to 0x4. In power-down mode, the EMIF does not stop the clocks to the SDRAM. The EMIF maintains CKE pin low to maintain the power-down mode.

When the SDRAM is in power-down mode, the EMIF services register accesses normally.

If the SDRAM is in power-down mode and one of the following occurs, the EMIF brings SDRAM out of power-down mode:

- EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is changed from 0x4 to some other value.
- An SDRAM access is requested.
- The refresh-must level is reached.

For DDR3, the EMIF also exits power-down mode to perform incremental leveling. If refresh-must brings EMIF out of Power-Down, it will reenter Power-Down when the refreshes are complete if there has not been a SDRAM request.

To exit power-down, the EMIF:

1. Drives CKE high after t_cke + 1 cycles have elapsed since the power-down command was issued. The value of t_cke is taken from EMIF_SDRAM_TIMING_2[2:0] T_CKE bit field.
2. Waits for EMIF_SDRAM_TIMING_2[30:28] T_XP + 1 cycles
3. Enters its idle state and can issue any commands

15.3.4.4.2 LPDDR2 Deep Power-Down Mode

For ultimate power savings, the EMIF supports deep power-down mode for LPDDR2.

The SDRAM can be forced into deep power-down mode through software by setting the EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN bit to 0x1. In this case the EMIF continues normal operation until all SDRAM access requests are serviced. At this point the EMIF issues a deep power-down command. The EMIF then maintains CKE pin low to maintain deep power-down mode. In deep power-down mode, the EMIF automatically stops the clocks to the SDRAM.

Setting the EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN bit to 1 overrides the setting of the EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field. Therefore, if the SDRAM is in any other power-saving mode, and the EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN bit is set to 1, the EMIF exits those modes and goes into deep power-down mode.

When the SDRAM is in deep power-down mode, the EMIF services register accesses normally.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

If the EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN bit is set to 0x0, the EMIF brings the SDRAM out of deep power-down mode.

For LPDDR2, the EMIF controller performs SDRAM initialization as specified in Section 15.3.4.7.1, *LPDDR2-SDRAM Initialization*. Note the initialization part that must be performed by the software.

15.3.4.4.3 Self-Refresh Mode

The EMIF supports self-refresh mode for low power. The EMIF automatically puts the SDRAM into self-refresh mode after the EMIF is idle for EMIF_POWER_MANAGEMENT_CONTROL[7:4] SR_TIMING number of DDR clock cycles and the EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is set to 0x2. The EMIF will complete all pending refreshes before it puts the SDRAM into self-refresh. Therefore, after the expiration of SR_TIMING, the EMIF will start issuing refreshes to complete the refresh backlog, and then issue a self-refresh command to the SDRAM.

In self-refresh mode, the EMIF automatically stops the clocks to the SDRAM. The EMIF drives CKE pin low to maintain self-refresh mode.

When the SDRAM is in self-refresh mode, the EMIF services register accesses normally.

If the SDRAM is in self-refresh mode and one of the following occurs, the EMIF brings SDRAM out of self-refresh mode:

- The EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is changed from 0x2 to some other value.
- SDRAM access is requested .

For DDR3, the EMIF also exits self-refresh to perform incremental leveling.

To exit self-refresh, for LPDDR2, the EMIF:

1. Waits for EMIF_SDRAM_TIMING_2[2:0] T_CKE + 1 cycles have elapsed since the self-refresh command was issued and enables clocks
2. Drives CKE pin high
3. Waits for EMIF_SDRAM_TIMING_2[24:16] T_XSNR + 1 cycles
4. Starts an auto-refresh cycle in the next cycle. It also services all refreshes down to the refresh-release level.
5. Enters its idle state and can issue any commands

To exit self-refresh, for DDR3, the EMIF:

1. Waits for EMIF_SDRAM_TIMING_2[2:0] T_CKE + 1 cycles have elapsed since the self-refresh command was issued and enables clocks
2. Drives CKE pin high
3. Waits for EMIF_SDRAM_TIMING_2[24:16] T_XSNR + 1 cycles
4. If EMIF_SDRAM_CONFIG[20] DDR_DISABLE_DLL is 1, issues a load mode register command to the extended mode register 1 (pins BA[2:0] = 0x1) with the A[15:0] pins set as inTable 15-103

Table 15-103. Extended Mode Register 1 Value

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Output buffer enabled
A[11]	0x0	TDQS disable
A[12]	0x0	Reserved
A[9]	DDR_TERM[2]	DDR3 termination resistor value from EMIF_SDRAM_CONFIG register, bit 26
A[8]	0x0	Reserved
A[7]	0x0	Write leveling disabled
A[6]	DDR_TERM[1]	DDR3 termination resistor value from EMIF_SDRAM_CONFIG register, bit 19

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 15-103. Extended Mode Register 1 Value (continued)

Bits	Value	Description
A[5]	SDRAM_DRIVE[1]	SDRAM drive strength from EMIF_SDRAM_CONFIG register, bit 25
A[4:3]	0x0	Additive latency = 0
A[2]	DDR_TERM[0]	DDR3 termination resistor value from EMIF_SDRAM_CONFIG register, bit 24
A[1]	SDRAM_DRIVE[0]	SDRAM drive strength from EMIF_SDRAM_CONFIG register, bit 18
A[0]	0x1	Disable DLL

5. Starts an auto-refresh cycle in the next cycle. It also services all refreshes down to the refresh-release level.
6. Enters its idle state and can issue any other commands except for a write or a read. A write or a read is issued only after EMIF_SDRAM_TIMING_2[15:6] T_XSRD + 1 cycles clock cycles have elapsed since pin CKE is driven high.

To use partial array self-refresh, the EMIF_SDRAM_REFRESH_CONTROL[26:24] PASR bits must be appropriately programmed. The EMIF performs bank interleaving when EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0x0. Because the SDRAM is partially refreshed during partial array self-refresh, for software ease, it is recommended that IBANK_POS be set to 1, 2, or 3 depending on the scheme used. If IBANK_POS is set to 0, software must move critical data into the banks that are going to be refreshed during partial array self-refresh.

15.3.4.4.4 Retention Mode

EMIF supports full-retention mode.

NOTE: It is a responsibility of the software to:

- Disable incremental leveling on entry into retention to avoid possible collision with SDRAM self refresh entry
- Enable incremental leveling or perform a full leveling upon exit of retention

15.3.4.5 Interrupt Requests

The EMIF sources two interrupts: one for the system and MPU local interfaces, and the other for the low-latency local interface. The pulse and level interrupt signals for a particular interface are sourced from the same raw interrupt internal to the module.

The EMIF sets the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[0] RAW_SYS/EMIF_LOW_LATENCY_OCP_INTERRUPT_RAW_STATUS[0] RAW_LL bit (depending on which interface sent the command having an error) to 1, if an access request to an unsupported MAddrSpace is received. If such an error occurs, it is due to bad programming of the DMM. For more information about addressing, see Section 15.2.1, *Dynamic Memory Manager*.

Table 15-104 lists the event flags and their mask that can cause module interrupts.

Table 15-104. Events

Event Flag	Event Mask	Description
EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[1] TA_SYS / EMIF_SYSTEM_OCP_INTERRUPT_STATUS[1] TA_SYS	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[1] EN_TA_SYS / EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[1] EN_TA_SYS	System interface interrupt for SDRAM temperature alert
EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[0] ERR_SYS / EMIF_SYSTEM_OCP_INTERRUPT_STATUS[0] ERR_SYS	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[0] EN_ERR_SYS / EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[0] EN_ERR_SYS	System interface interrupt for command or address error

PRELIMINARY

15.3.4.6 SDRAM Refresh Scheduling

The EMIF uses two counters to schedule AUTO REFRESH commands: a 13-bit decrementing refresh interval counter and a 4-bit refresh backlog counter. The interval counter is used to define the rate at which connected SDRAM devices are refreshed. It is loaded with the value of the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field at reset (only the 13 LSBs are taken). The interval counter decrements by 1 each cycle until it reaches 0, at which point it reloads from the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field and restarts decrementing. The counter also reloads and restarts decrementing whenever the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field is updated.

The refresh backlog counter records the number of outstanding AUTO REFRESH commands the EMIF has. The backlog counter increments by 1 each time the interval counter reloads (unless it has reached its maximum value of 8). The backlog counter decrements by 1 each time the EMIF issues an AUTO REFRESH command (unless it is already 0). For the range of values that the backlog counter can take, there are three levels of urgency with which the EMIF must perform an auto refresh cycle (in which it issues AUTO REFRESH commands):

1. Refresh-may level is reached when the backlog count is greater than 0, which indicates there is a refresh backlog; therefore, if the EMIF is not busy and none of the SDRAM banks are open, the EMIF must perform an auto refresh cycle.
2. Refresh-release level is reached when the backlog count is greater than 4, which indicates the refresh backlog is getting bigger; therefore, if the EMIF is not busy it must perform an auto refresh cycle even if any of the banks are open.
3. Refresh-must level is reached when the backlog count is greater than 7, which indicates the refresh backlog is becoming excessive and the EMIF must perform an auto refresh cycle before servicing any new memory access requests. The EMIF starts servicing new memory accesses after the refresh-release level is cleared.

The refresh counters do not operate when SDRAM is in self-refresh mode. Also, the refresh counters start tracking the missed refreshes only after initialization is complete in case of DDR3. For LPDDR2, the refresh counters will start tracking missed refreshes after the RESET command is issued.

The EMIF issues AUTO REFRESH commands within auto refresh cycles. An auto refresh cycle consists of issuing an AUTO REFRESH command and waiting T_RFC (see EMIF_SDRAM_TIMING_3) cycles before rechecking the refresh levels. If the refresh-release level is not reached, the EMIF starts another auto refresh cycle; otherwise, it returns to idle mode where it can issue any command. The EMIF ensures that no more than eight AUTO REFRESH commands are issued in any rolling t_{REFBW} (= 4 × 8 × t_{RFC}) window.

15.3.4.7 SDRAM Initialization

15.3.4.7.1 LPDDR2 SDRAM Initialization

When coming out of reset, if the EMIF_SDRAM_CONFIG[31:29] SDRAM_TYPE bit field is equal to 4, the EMIF performs an LPDDR2 initialization sequence as follows:

1. Drives the CKE pin high and starts to issue NOP commands continuously
2. After 17 SDRAM refresh rate intervals, issues a PRECHARGE-ALL command. The SDRAM refresh rate is defined in the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field.
3. Issues a RESET command
4. Software must initialize LPDDR2 using the EMIF_LPDDR2_MODE_REG_CONFIG and EMIF_LPDDR2_MODE_DATA registers. Software must enable refreshes by writing 1 in the EMIF_LPDDR2_MODE_REG_CONFIG[30] REFRESH_EN bit during the last MRW command.

The EMIF also performs the initialization sequence whenever the EMIF_SDRAM_CONFIG register is written and the LPDDR2 initialization was not performed previously because the EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS bit was set to 0. Once the EMIF performs initialization, rewriting the EMIF_SDRAM_CONFIG/EMIF_SDRAM_CONFIG_2 configuration registers does not cause reinitialization.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: The values of the bit fields in the EMIF_SDRAM_CONFIG and EMIF_SDRAM_CONFIG_2 registers are loaded by the control module at reset. These values can be modified by the configuration header (CH) feature of the ROM code or by the initial boot image running from an external XIP booting memory or internal RAM (see Section 28.3.8, *Image Format*). They must not be modified during run time, because they reflect the used hardware SDRAM memory configurations.

The EMIF does not perform any transactions until the LPDDR2 initialization sequence completes.

When the EMIF comes out of reset, the delay time in Step 2 resulting from the 17 refresh rate intervals + 8 cycles is approximately 17 × EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE / input frequency.

15.3.4.7.2 DDR3 Initialization

On coming out of reset, if EMIF_SDRAM_CONFIG[31:29] SDRAM_TYPE is equal to 3 and EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS bit is set to 0, the EMIF performs a DDR3 SDRAM initialization sequence as follows:

1. Drives the CKE pin low
2. After 17 SDRAM refresh rate intervals, issues a NOP command with CKE pin held high. The SDRAM refresh rate is as defined in the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field.
3. After one SDRAM refresh rate interval, issues a LOAD MODE REGISTER command to the extended mode register 2 (pins BA[2:0] = 0x2) with pins A[15:0] set as in Table 15-105

Table 15-105. Extended Mode Register 2 Value

Bits	Value	Description
A[15:11]	0x0	Reserved
A[10:9]	DYN_ODT[1:0]	Dynamic ODT value from EMIF_SDRAM_CONFIG[22:21] DYN_ODT. Dynamic ODT is NOT supported. Set to 0x0 in the register bitfield.
A[8]	0x0	Reserved
A[7]	SRT	Self-refresh temperature range from EMIF_SDRAM_REFRESH_CONTROL[29] SRT
A[6]	ASR	Auto self-refresh enable from EMIF_SDRAM_REFRESH_CONTROL[28] ASR
A[5]	0x0	Reserved
A[4:3]	CWL[1:0]	CAS write latency from EMIF_SDRAM_CONFIG[17:16] CWL
A[2:0]	PASR[2:0]	Partial array self-refresh from EMIF_SDRAM_REFRESH_CONTROL[26:24] PASR

4. Issues a LOAD MODE REGISTER command to the extended mode register 3 (pins BA[2:0] = 0x3) with A[15:0] = 0x0
5. Issues a LOAD MODE REGISTER command to the extended mode register 1 (BA[2:0] = 0x1) with A[15:0] set as in Table 15-106

Table 15-106. Extended Mode Register 1 Value

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Output buffer enabled
A[11]	0x0	TDQS disable
A[10]	0x0	Reserved

Table 15-106. Extended Mode Register 1 Value (continued)

Bits	Value	Description
A[6]	DDR_TERM[1]	DDR3 termination resistor value from EMIF_SDRAM_CONFIG[25] DDR_TERM
A[5]	SDRAM_DRIVE[1]	SDRAM drive strength from EMIF_SDRAM_CONFIG[19] SDRAM_DRIVE
A[4:3]	0x0	Additive latency = 0
A[2]	DDR_TERM[0]	DDR3 termination resistor value from EMIF_SDRAM_CONFIG[24] DDR_TERM
A[1]	SDRAM_DRIVE[0]	SDRAM drive strength from EMIF_SDRAM_CONFIG[18] SDRAM_DRIVE
A[0]	0x0	Enable SDRAM DLL

6. Issues a LOAD MODE REGISTER command to the mode register 0 (BA[2:0] = 0x0) with A[15:0] set as in Table 15-107

Table 15-107. Mode Register 0 Value

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Fast exit active power-down exit time
A[11:9]	T_WR[4:0]	Write recovery for auto pre-charge from EMIF_SDRAM_TIMING_1[20:17] T_WR
A[8]	0x1	DLL reset
A[7]	0x0	Normal mode
A[6:4]	CL[3:1]	CAS latency from EMIF_SDRAM_CONFIG[13:11] CL
A[3]	0x0	Sequential burst type
A[2]	CL[0]	CAS latency from EMIF_SDRAM_CONFIG[10] CL
A[1:0]	0x0	Burst length of 8

7. Issues a ZQCL command to start long ZQ calibration
8. Waits for t_{DLLK} and t_{ZQinit} to complete
9. If the EMIF_SDRAM_CONFIG[20] DDR_DISABLE_DLL bit is 1, issues a LOAD MODE REGISTER command to the extended mode register 1 (BA[2:0] = 0x1) with A[15:1] set as in Table 15-106 (Step 5) and A[0] set to 0x1.
10. Issues an AUTO REFRESH command
11. The EMIF enters its IDLE state.

The EMIF also performs the initialization sequence whenever the EMIF_SDRAM_CONFIG register is written. But in this case, the EMIF starts from Step 3.

The EMIF does not perform any transactions until the DDR3 initialization sequence is complete.

NOTE: The LOAD MODE REGISTER command may be referred to as MODE REGISTER SET command in some DDR3 datasheets.

When the EMIF comes out of reset, the delay time in Step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately 17 × REFRESH_RATE / input frequency.

15.3.4.8 DDR3 Read-Write Leveling

The EMIF supports two types of write/read leveling:

- Full leveling
- Incremental leveling

Each leveling type has three parts:

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

1. Write leveling
2. Read DQS gate training
3. Read data eye training

15.3.4.8.1 Full Leveling

The EMIF does not perform full leveling after initialization upon reset. Full leveling must be triggered by software after the EMIF registers are properly configured. The EMIF also supports triggering of full leveling through software through the use of the EMIF_READ_WRITE_LEVELING_CONTROL[31] RDWRLVLFULL_START bit.

Full leveling will be interrupted by auto refresh if a refresh-must state is reached. Upon completion of the auto refresh, full leveling will be reentered at the point it exited and continue until completion.

15.3.4.8.2 Incremental Leveling

The EMIF supports incremental leveling to better track voltage and temperature changes during normal operation. The incremental leveling can be enabled by writing a non-zero value to the following bit fields in the EMIF_READ_WRITE_LEVELING_CONTROL register:

- [7:0] WRLVLINC_INT
- [15:8] RDLVLGATEINC_INT
- [23:16] RDLVLINC_INT

The EMIF periodically triggers incremental write leveling every time WRLVLINC_INT expires. In other words, the WRLVLINC_INT defines the interval between successive incremental write leveling.

Similarly, the EMIF periodically triggers incremental read DQS gate training every time RDLVLGATEINC_INT expires, and triggers incremental read data eye training every time RDLVLINC_INT expires. To minimize impact on bandwidth, the software can program these intervals such that these three intervals do not expire at same time. The value of interval programmed is dependent on the slope of voltage and temperature changes.

The EMIF supports increasing the rate of incremental leveling automatically for a defined period of time. This can be achieved by programming the EMIF_READ_WRITE_LEVELING_RAMP_CONTROL register and by using a signal to increase the rate of incremental leveling from PHY. Whenever a signal is received, the EMIF uses the intervals programmed in the EMIF_READ_WRITE_LEVELING_RAMP_CONTROL register until the ramp window in the EMIF_READ_WRITE_LEVELING_RAMP_WINDOW[12:0] RDWRLVLINC_RMP_WIN bit field expires. After the expiration, the EMIF switches back to use the intervals programmed in the EMIF_READ_WRITE_LEVELING_CONTROL register. To ensure none of the incremental leveling events are missed, the EMIF_READ_WRITE_LEVELING_RAMP_WINDOW[12:0] RDWRLVLINC_RMP_WIN bit field must be programmed greater than the intervals in the EMIF_READ_WRITE_LEVELING_RAMP_CONTROL register.

If the EMIF is in self-refresh or power-down mode when any of the incremental leveling intervals expire, the EMIF exits self-refresh or power-down mode, perform the required leveling, and then re-enter the exited mode.

15.3.4.9 EMIF Access Cycles

By default, the EMIF keeps the SDRAM CSs high (CSs are active-low signals). To direct a command to only one of the SDRAMs, the EMIF asserts the CS to the SDRAM for the duration of the command. If the EMIF_SDRAM_CONFIG[3] EBANK bit in the SDRAM configuration register is set to 0, NCS1 is always driven high except during initialization and for the REFRESH, POWER-DOWN, SELF-REFRESH, and DEEP POWER-DOWN commands.

The EMIF always performs burst accesses to the SDRAM. Multiple SDRAM bursts may be needed to service a single local burst request. Table 15-108 through Table 15-112 show a few examples of how EMIF accesses SDRAM for a linear incrementing transaction type. T0, T1, etc. are clock cycles. R0 is read starting at column 0, R8 is read starting at column 8, and R16 is read starting at column 16. D0-1 is the data from column 0 and 1, D2-3 is the data from column 2 and 3, and so on.

The EMIF uses the unused data phases in the preceding figures by issuing successive read commands if there are reads to open banks pending in the command FIFO.

The write data conversion from SDR to DDR is done outside the EMIF.

15.3.4.9.1 LPDDR2 Read

A read access to an LPDDR2 is initiated with a READ command. The EMIF provides the internal bank address and the column address on pins CA[9:0] with the READ command. The EMIF registers the first read data from DQ[31:0] after (EMIF_DDR_PHY_CONTROL_1[4:0] READ_LATENCY) DDR clock cycles.

15.3.4.9.2 LPDDR2 Write

A write access to an LPDDR2 is initiated with a WRITE command. The EMIF provides the internal bank address and the column address on pins CA[9:0] with the WRITE command.

The EMIF delays the write data by the appropriate write latency minus 1. Subsequent data words are provided on DQ[31:0] along with the appropriate data mask on DM[3:0] on each successive clock cycle. The DDR PHY then adds one more clock cycle delay to the write data to appropriately center the write data to the outgoing DQS.

15.3.4.10 Turnaround Time

Table 15-113 lists the turnaround time the EMIF introduces on the data bus for various back-to-back accesses. The EMIF takes advantage of the CAS latencies and packs the commands as close as possible on the control bus to introduce the following turnaround time on the data bus.

Table 15-113. Turnaround Time

Current Access	Next Access	Turnaround Time (Number of DDR Clock Cycles)
SDRAM write	SDRAM write to the same CS	0
SDRAM write	SDRAM write to a different CS	EMIF_SDRAM_TIMING_3[27:24] T_CSTA + 1
SDRAM read	SDRAM read to the same CS	0
SDRAM read	SDRAM read to a different CS	EMIF_SDRAM_TIMING_3[27:24] T_CSTA + 1
SDRAM write	SDRAM read	EMIF_SDRAM_TIMING_1[2:0] T_WTR + 1 + CL
SDRAM read	SDRAM write	EMIF_SDRAM_TIMING_1[31:29] T_RTW + 1

15.3.4.11 PHY DLL Calibration

When running in normal locked mode, the PHY DLL gets a reference clock (EMIFi_DLL_FCLK) from the PRCM, which is used by the DLL master to lock to the right frequency and provide the control code for a full period phase shift to the slave. The slave uses this code as a control for its internal delay line to produce the required delay for the signal considered.

When working in locked mode, the delay lines only get an updated control value from the master DLLs when an explicit dll_calib command is issued by the EMIF controller. Failure to send such commands on a timely basis will result in inaccurate delay-line information if there is a significant voltage and temperature drift in the system. It is recommended to issue at least one command every 100 µs. EMIF automatically sends ctrl_update commands for:

- Refresh Exit
- Self Refresh Exit
- phy_ready asserted during initialization

The PHY also internally generates a control value update upon completion of a leveling operation. Control is also added for the when leveling is not used (that is, not using ramp reg_rdwrlvlinc_rmp_win, which generates increased level of incremental leveling and an internally generated phy calib signal), and there are gradual voltage changes during frequency change. The EMIF_DLL_CALIB_CTRL register can be programmed to generate a phy_dll_calib for a periodic interval based on EMIF_COREi cycles, so allow continued memory access as voltage is changing. A safe window of no activity will be guaranteed for this periodic generation of phy_dll_calib. In addition, a one shot generator for phy_pll_calib has also been added that will generate a single phy_dll_calib by setting the EMIF_MISC_REG[0] DLL_CALIB_OS bit to 1.

15.3.4.12 SDRAM Address Mapping

The EMIF interleaves the internal banks for SDRAM connected to both CSs (see Table 15-114 for the SDRAM addressing space), according to the DMM (for more information, see Section 15.2.1, *Dynamic Memory Manager*). From the system point of view, the external SDRAM is seen as one block of SDRAM. If two external 64-MiB devices are used, a 128-MiB memory block is observed. If two external 32-MiB devices are used, a 64-MiB block is observed.

Table 15-114. SDRAM Addressing Space

Module Name	Base Address	Size
EMIF1 | EMIF2-CS0-SDRAM[(1)]	0x8000 0000	0 to 1GiB, programmable in DMM (see Section 15.2.1, *Dynamic Memory Manager*)

(1) The addressing space is interleaved on two SDRAM memory controllers (EMIF1, EMIF2), each activating itsCS0 line. These CSs can address 64, 128, 256, 512, 1024, or 2048MiB. Interleaving occurs at 128-byte granularity. EMIF1-CS0 base address is always 0x8000 0000 at reset, and occupies a 1-GiB address space at reset (interleaving disabled at reset).

PRELIMINARY

Table 15-114. SDRAM Addressing Space (continued)

Module Name	Base Address	Size
EMIF1| EMIF2-CS1-SDRAM[2]	0xC000 0000	0 to 1GiB, programmable in DMM (see Section 15.2.1, *Dynamic Memory Manager*)

[2] The addressing space is interleaved on two SDRAM memory controllers (EMIF1, EMIF2), each activating its CS1 line. These CSs are programmable to 64, 128, 256, 512, or 1024MiB. Interleaving occurs at 128-byte granularity. EMIF1-CS1 and EMIF2-CS1 are disabled at reset. Their base address is programmable to achieve a continuous address space with the respective CS0, regardless of the programmed address range. EMIF1-CS1 is disabled if the EMIF1-CS0 memory density is set to 2048MiB (2GiB) when interleaving is disabled, or if the EMIF1-CS0 + EMIF2-CS0 memory density is set to 1024MiB (1GiB) when interleaving is enabled.

When addressing SDRAM, if the EMIF_SDRAM_CONFIG[28:27] IBANK_POS bit field is set to 0, the EMIF uses the following three bit fields to determine the mapping from the source address to the SDRAM row, column, bank, and CS:

- EMIF_SDRAM_CONFIG[6:4] IBANK
- EMIF_SDRAM_CONFIG[3] EBANK
- EMIF_SDRAM_CONFIG[2:0] PAGESIZE

If the EMIF_SDRAM_CONFIG[28:27] IBANK_POS bit field is set to 1, 2, or 3, the EMIF uses the following four bit fields to determine the mapping from the source address to the SDRAM row, column, bank, and CS:

- EMIF_SDRAM_CONFIG[6:4] IBANK
- EMIF_SDRAM_CONFIG[3] EBANK
- EMIF_SDRAM_CONFIG[2:0] PAGESIZE
- EMIF_SDRAM_CONFIG[9:7] ROWSIZE

In all cases the EMIF considers its SDRAM address space to be a single logical block, regardless of the number of physical devices or whether the devices are mapped across one or two EMIF CSs.

15.3.4.12.1 Address Mapping for IBANK_POS = 0 and EBANK_POS = 0

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0 and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 0, Table 15-115 lists which source address bits (MAddr) map to the SDRAM row, column, bank, and CS bits for all combinations of IBANK, EBANK, and PAGESIZE.

NOTE: ROWSIZE is unused in case of IBANK_POS = 0 and EBANK_POS = 0.

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, the effect of the address-mapping scheme is that as the source address increments across SDRAM page boundaries, the EMIF moves onto the same page in the next bank in the current device (pin CS0). This movement along the banks of the current device continues until the page is accessed in all banks in the current device. The EMIF then proceeds to the same page in the next device (if EMIF_SDRAM_CONFIG[3] EBANK = 1, pin CS1) and proceeds through the same page in all its banks before moving to the next page in the first device (pin CS0). The EMIF exploits this movement across internal banks and CSs while remaining on the same page to maximize the number of open SDRAM banks within the overall SDRAM space.

Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, and can interleave among all of them.

15.3.4.12.2 Address Mapping for IBANK_POS = 1 and EBANK_POS = 0

Table 15-116 list the local address to SDRAM address mapping. There are x bits for bank[2], followed by y bits for row, followed by z bits for CS, followed by s bits for bank[1:0], and t bits for col in MAddr[31:2] (x, y, z, s, and t are given depending on the value of the EMIF_SDRAM_CONFIG bit fields).

		4	13						
		5	14						
		6	15						
		7	16						

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 1, the EMIF interleaves banks the same as for EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, but the interleaving of banks within a device (per CS) is limited to four banks. Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but can interleave among only 8 of them.

15.3.4.12.3 Address Mapping for IBANK_POS = 2 and EBANK_POS = 0

Table 15-117 list the local address to SDRAM address mapping. There are x bits for bank[2:1], followed by y bits for row, followed by z bits for CS, followed by s bits for bank[0], and t bits for col in MAddr[31:2] (x, y, z, s, and t are given depending on the value of the EMIF_SDRAM_CONFIG bit fields).

Table 15-117. Local Address to SDRAM Address Mapping for IBANK_POS = 2 and EBANK_POS = 0

MAddr[31:2]									
bank[2:1]		row		cs		bank[0]		col	
IBANK	bank[2:1] width (bits)	ROWSIZE	row width (bits)	EBANK	cs width (bits)	IBANK	bank[0] width (bits)	PAGESIZE	col width (bits)
0	0	0	9	0	0	0	0	0	8
1	0	1	10	1	1	1	1	1	9
2	1	2	11			2	1	2	10
3	2	3	12			3	1	3	11
		4	13						
		5	14						
		6	15						
		7	16						

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 2, the EMIF interleaves banks the same as for EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, but the interleaving of banks within a device (per CS) is limited to two banks. Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but can interleave among only 4 of them.

15.3.4.12.4 Address Mapping for IBANK_POS = 3 and EBANK_POS = 0

Table 15-118 list the local address to SDRAM address mapping. There are x bits for bank, followed by y bits for row, followed by z bits for CS, and t bits for col in MAddr[31:2] (x, y, z, s, and t are given depending on the value of the EMIF_SDRAM_CONFIG bit fields).

				5	14				
				6	15				
				7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 1, and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the EMIF interleaves banks the same as for EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, but the interleaving of banks within a device (per CS) is limited to four banks. Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but can interleave among only 4 of them.

15.3.4.12.7 Address Mapping for IBANK_POS = 2 and EBANK_POS = 1

Table 15-121 list the local address to SDRAM address mapping. There are z bits for CS, followed by x bits for bank[2:1], followed by y bits for row, followed by s bits for bank[0],and t bits for col in MAddr[31:2] (x, y, z, s, and t are given depending on the value of the EMIF_SDRAM_CONFIG bit fields).

Table 15-121. Local Address to SDRAM Address Mapping for IBANK_POS = 2 and EBANK_POS = 1

MAddr[31:2]									
cs		bank[2:1]		row		bank[0]		col	
EBANK	cs width (bits)	IBANK	bank[2:1] width (bits)	ROWSIZE	row width (bits)	IBANK	bank[0] width (bits)	PAGESIZE	col width (bits)
0	0	0	0	0	9	0	0	0	8
1	1	1	0	1	10	1	1	1	9
		2	1	2	11	2	1	2	10
		3	2	3	12	3	1	3	11
				4	13				
				5	14				
				6	15				
				7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 2 and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the EMIF interleaves banks the same as for EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, but the interleaving of banks within a device (per CS) is limited to two banks. Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but can interleave among only two of them.

15.3.4.12.8 Address Mapping for IBANK_POS = 3 and EBANK_POS = 1

list the local address to SDRAM address mapping. There are z bits for CS, followed by x bits for bank, followed by y bits for row, and t bits for col in MAddr[31:2] (x, y, z and t are given depending on the value of the EMIF_SDRAM_CONFIG bit fields).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 15-122. Local Address to SDRAM Address Mapping for IBANK_POS = 3 and EBANK_POS = 1

MAddr[31:2]							
cs		bank		row		col	
EBANK	cs width (bits)	IBANK	bank width (bits)	ROWSIZE	row width (bits)	PAGESIZE	col width (bits)
0	0	0	0	0	9	0	8
1	1	1	1	1	10	1	9
		2	2	2	11	2	10
		3	3	3	12	3	11
				4	13		
				5	14		
				6	15		
				7	16		

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 3 and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the EMIF cannot interleave banks within a device (per CS). Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but cannot interleave among them.

NOTE: Because the EMIF interleaves among a fewer number of banks when EMIF_SDRAM_CONFIG[28:27] IBANK_POS ≠ 0 or EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, these cases are lower in performance than the EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0 case. Thus, these cases are recommended to be used only with partial array self-refresh where performance can be traded off for power savings.

15.3.4.13 Output Impedance Calibration

The EMIF supports automatic output impedance calibration. The ZQ calibration can be enabled per CS by setting the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[31] ZQ_CS1EN and EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[30] ZQ_CS0EN bits. The EMIF supports three types of ZQ calibration commands:

- ZQINIT: ZQ calibration command during initialization
- ZQCS: ZQ calibration short command
- ZQCL: ZQ calibration long command

For DDR3, the EMIF automatically issues a ZQINIT command during initialization. For LPDDR2, software must issue a ZQINIT command (MRW to mode register 10). EMIF waits and blocks any other command for (ZQ_ZQINIT_MULT + 1) × (ZQ_ZQCL_MULT + 1) × (ZQ_ZQCS + 1) number of DDR clock cycles every time a ZQINIT command is issued. The bit fields used are:

- EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[19:18] ZQ_ZQINIT_MULT
- EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[17:16] ZQ_ZQCL_MULT
- EMIF_SDRAM_TIMING_3[20:15] ZQ_ZQCS

The EMIF issues a ZQCS command each time the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[15:0] ZQ_REFINTERVAL bit field expires. In other words, the ZQ_REFINTERVAL defines the interval between ZQCS commands. When a ZQCS command is issued, the EMIF waits and blocks any other command for (EMIF_SDRAM_TIMING_3[20:15] ZQ_ZQCS + 1) number of DDR clock cycles.

If the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[28] ZQ_SFEXITEN bit field is set to 1, the EMIF issues a ZQCL command every time it exits self-refresh modes. When a ZQCL command is issued, the EMIF waits and blocks any other command for (EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[17:16] ZQ_ZQCL_MULT + 1) × (EMIF_SDRAM_TIMING_3[20:15] ZQ_ZQCS + 1) number of DDR clock cycles.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

If a separate calibration resistor is used per device, the ZQ calibration can be performed simultaneously over both CSs. To enable ZQ calibration to be performed simultaneously over both CSs, the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[27] ZQ_DUALCALEN bit must be set to 1. If ZQ_DUALCALEN is set to 0, the EMIF performs ZQ calibration per CS serially.

15.3.4.14 LPDDR2 Temperature Monitoring

The EMIF supports automatic temperature monitoring to facilitate the software update of the refresh rate according to the temperature changes of the LPDDR2. Temperature monitoring can be enabled per CS by setting the EMIF_TEMPERATURE_ALERT_CONFIG[31] TA_CS1EN and EMIF_TEMPERATURE_ALERT_CONFIG[30] TA_CS0EN bits.

The EMIF polls the temperature of the LPDDR2 (issues an MRR command to mode register 4) every time the EMIF_TEMPERATURE_ALERT_CONFIG[21:0] TA_REFINTERVAL bit field expires. In other words, TA_REFINTERVAL defines the interval between temperature alert polls. If the EMIF sees a 1 on bit 7 of the read data value from the MRR, which indicates the temperature has changed, the EMIF_SYSTEM_OCP_INTERRUPT_STATUS[1] TA_SYS bit (for system interface) and EMIF_LOW_LATENCY_OCP_INTERRUPT_STATUS[1] TA_LL bit (for low-latency interface) are set and the module sends an interrupt on the system and low-latency interrupt lines, respectively. When the interrupt is received, software must update the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field to the required value as per the temperature change.

If the EMIF_TEMPERATURE_ALERT_CONFIG[28] TA_SFEXITEN bit is set to 1, the EMIF polls for temperature change every time it exits self-refresh, active power-down, and precharge power-down modes.

Because the EMIF is performing an MRR, it needs information about how the LPDDR2 is connected. The EMIF_TEMPERATURE_ALERT_CONFIG[27:26] TA_DEVWDT and EMIF_TEMPERATURE_ALERT_CONFIG[25:24] TA_DEVCNT bit fields provide the necessary information to the EMIF for MRR data compare. For example, if TA_DEVWDT is set to 0, which indicates 8-bit devices are used, and if TA_DEVCNT is set to 2, which indicates four devices are used to form a 32-bit bus, the mask used for checking is 4'b1111; that is, the EMIF expects data on each byte lane on a 32-bit bus.

15.3.4.15 Performance Counters

The EMIF_PERFORMANCE_COUNTER_1 and EMIF_PERFORMANCE_COUNTER_2 registers can be used to monitor or calculate the EMIF bandwidth and efficiency. These counters can count events such as total SDRAM accesses, SDRAM activates, reads, writes, etc. Each counter counts events independent of the other counters. In addition to the ability to count events, the counters can also filter the events from a particular master or address space. The events to be counted and the filter enabling can be configured using the EMIF_PERFORMANCE_COUNTER_CONFIG register. The filter value to be used can be configured using the EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT register. Each counter can be configured independently.

Table 15-123 lists all the events that can be counted and whether a filter can be applied to a particular event. A filter can be applied to an event if the following bits for Performance Counter 1 and Performance Counter 2 can be set equal to 0x1 for that event:

- Performance Counter 1: EMIF_PERFORMANCE_COUNTER_CONFIG[15] CNTR1_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[14] CNTR1_REGION_EN
- Performance Counter 2: EMIF_PERFORMANCE_COUNTER_CONFIG[31] CNTR2_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[30] CNTR2_REGION_EN

Table 15-123. Performance Counter Filter Configuration

CNTRn_CFG[1]	CNTRn_REGION_EN	CNTRn_MCONNID_EN	Description
0x0	0x0	0x0 or 0x1	Count total SDRAM accesses
0x1	0x0	0x0 or 0x1	Count total SDRAM activates
0x2	0x0 or 0x1	0x0 or 0x1	Count total reads
0x3	0x0 or 0x1	0x0 or 0x1	Count total writes

(1) n = 1 or 2

PRELIMINARY

Table 15-123. Performance Counter Filter Configuration (continued)

CNTRn_CFG[1]	CNTRn_REGION_EN	CNTRn_MCONNID_EN	Description
0x4	0x0	0x0	Count number of EMIF_COREi clock cycles local Command FIFO is full
0x5	0x0	0x0	Count number of EMIF_COREi clock cycles local Write Data FIFO is full
0x6	0x0	0x0	Count number of EMIF_COREi clock cycles local Read Data FIFO is full
0x7	0x0	0x0	Count number of EMIF_COREi clock cycles local Return Command FIFO is full
0x8	0x0 or 0x1	0x0 or 0x1	Count number of priority elevations
0x9	0x0	0x0	Count number of EMIF_COREi clock cycles that a command was pending
0xA	0x0	0x0	Count number of EMIF_COREi clock cycles for which the memory data bus was transferring data.
0xB - 0xF	0x0	0x0	Reserved for future use.

NOTE: When MReqDebug is set to 1 for a particular local command, the performance counters are not incremented for that particular command if the CNTRn_CONFIG values are equal to 0x0, 0x1, 0x2, 0x3, or 0xA.

Table 15-123 shows the possible filter configurations for the two performance counters. These filter configurations can be used in conjunction with a local master ID and/or an external chip-select to obtain performance statistics for a particular local master and/or an external chip-select.

The EMIF clock frequency is half the DDR speed.

15.3.4.15.1 Performance Counters General Examples

15.3.4.15.1.1 PERF_COUNTER_1 General Example for Counting Write Accesses

The Performance Counter 1 register must count all write accesses from the IPU subsystem:

- To enable counting writes, the EMIF_PERFORMANCE_COUNTER_CONFIG[3:0] CNTR1_CONFIG bit field must be set to 0x3.
- The EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT[15:8] MCONNID1 bit field must be set to 0x44. The values programmed into the MCONNIDx bit fields are those in *ConnID Mapping (Debug View)*, in , *On-Chip Debug Support*, left-shifted by 2 bits.
- To enable filtering, the EMIF_PERFORMANCE_COUNTER_CONFIG[15] CNTR1_MCONNID_EN bit must be set to 0x1.

With this configuration, Counter 1 counts every write made to the EMIF from master 0x44 to any address space. This does not include accesses from other masters and does not include commands other than writes.

15.3.4.15.1.2 PERF_COUNTER_2 General Example for Counting Total Access

The Performance Counter 2 register must count total accesses to SDRAM regardless of the masters or address space.

- To enable counting all SDRAM accesses, the EMIF_PERFORMANCE_COUNTER_CONFIG[19:16] CNTR2_CONFIG bit field must be set to 0x0.
- To disable filtering, the EMIF_PERFORMANCE_COUNTER_CONFIG[31] CNTR2_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[30] CNTR2_REGION_EN bits must be set to 0x0.

With this configuration, Counter 2 counts every access made to the EMIF. This includes all accesses from all masters and to any address space.

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

15.3.4.15.1.3 PERF_COUNTER_3 General Example for Counting all Read Accesses

The Performance Counter 1 register must count all read accesses from the IPU subsystem to address space 0x0.

- To enable counting reads, the EMIF_PERFORMANCE_COUNTER_CONFIG[3:0] CNTR1_CONFIG bit field must be set to 0x2.
- The EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT[15:8] MCONNID1 and EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT[1:0] REGION_SEL1 bit fields must be set to 0x44 and 0x0, respectively.
- To enable filtering, the EMIF_PERFORMANCE_COUNTER_CONFIG[15] CNTR1_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[14] CNTR1_REGION_EN bits must be set to 0x1.

With this configuration, Counter 1 counts every read made to the EMIF from master 0x44 to address space 0x0. This does not include accesses from other masters or accesses to other address space and does not include commands other than reads.

15.3.5 EMIF Programming Guide

15.3.5.1 EMIF Low-Level Programming Models

This section describers the low-level hardware programming sequences for the configuration and use of the EMIF module.

The following programming sequences are doubled, when the two EMIF modules (EMIF1 and EMIF2) are used.

15.3.5.1.1 Global Initialization

Table 15-124. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. See Section 3.1.1, *Power, Reset, and Clock Management*.
Interrupt submodule of the MPU	The interrupt requests from the EMIF must be enabled (unmasked). See Section 17.1, *Interrupt Controllers*.
DMM	The EMIF is a slave to the DMM. The DMM must be enabled and configured for communication with LPDDR2 memories. See Section 15.2.1, *Dynamic Memory Manager*.

15.3.5.1.1.1 EMIF Module Global Initialization

This procedure initializes the EMIF after a power-on reset. The unused bits in all registers should be written with zeros. The values of the shadow registers are loaded in their corresponding registers a frequency update sequence is performed.

Table 15-125. EMIF Global Initialization

Step	Register/ Bit Field / Programming Model	Value
Assign the external bank address bits from lower or higher L3 address as shown in Section 15.3.4.12, *SDRAM Address Mapping*.	EMIF_SDRAM_CONFIG_2[27] EBANK_POS	0x-
Select the SDRAM type (LPDDR2 S2 or S4, or DDR3)	EMIF_SDRAM_CONFIG[31:29] SDRAM_TYPE	0x-
Assign internal bank address bits from L3 address as shown in Section 15.3.4.12, *SDRAM Address Mapping*.	EMIF_SDRAM_CONFIG[28:27] IBANK_POS	0x-
Choose 32-bit SDRAM data bus.	EMIF_SDRAM_CONFIG[15:14] NARROW_MODE	0x0
Define CAS latency when accessing connected SDRAM devices.	EMIF_SDRAM_CONFIG[13:10] CL	0x-
Define the number of row address bits of connected SDRAM device.	EMIF_SDRAM_CONFIG[9:7] ROWSIZE	0x-
Define the number of banks inside connected SDRAM device.	EMIF_SDRAM_CONFIG[6:4] IBANK	0x-
Define whether SDRAM accesses use 1 or 2 chip-select lines.	EMIF_SDRAM_CONFIG[3] EBANK	0x-
Define the internal page size of connected SDRAM device.	EMIF_SDRAM_CONFIG[2:0] PAGESIZE	0x-
Configure the DDR PHY-specific settings. Refer to register descriptions of EMIF_DDR_PHY_CONTROL_1, and EMIF_EXT_PHY_CONTROL_1 through EMIF_EXT_PHY_CONTROL_24	EMIF_DDR_PHY_CONTROL_1, and EMIF_EXT_PHY_CONTROL_1 through EMIF_EXT_PHY_CONTROL_24	0x-
Initialize MR LPDDR2 registers	External LPDDR2 initialization, seeTable 15-128	
Define timings and clock parameters	EMIF Timing Initialization, see Table 15-126

15.3.6 EMIF Register Manual

Table 15-140 lists the EMIF instance.

15.3.6.1 EMIF Instance Summary

Table 15-140. EMIF Instance Summary

Module Name	Base Address	Size
EMIF1	0x4C00 0000	16 MiB
EMIF2	0x4D00 0000	16 MiB

15.3.6.2 EMIF Registers

Many register values are programmed with full-speed DDR clock cycles, whereas EMIF always runs at half the speed of this clock. Because EMIF is only capable of decrementing these values at half speed (taking into account the minus 1 programming model) the following model applies for data issued on a lower bus:

- REG_VALUE = 0 → 2 DDR clocks
- REG_VALUE = 1 → 2 DDR clocks
- REG_VALUE = 2 → 4 DDR clocks
- REG_VALUE = 3 → 4 DDR clocks
- REG_VALUE = 4 → 6 DDR clocks
- REG_VALUE = 5 → 6 DDR clocks
- REG_VALUE = 6 → 8 DDR clocks
- REG_VALUE = 7 → 8 DDR clocks

Activate and deactivate commands use the upper bus. Register values associated with these operations follow the general rule:

- REG_VALUE = 0 → 1 DDR clocks
- REG_VALUE = 1 → 2 DDR clocks
- REG_VALUE = 2 → 2 DDR clocks
- REG_VALUE = 3 → 4 DDR clocks
- REG_VALUE = 4 → 4 DDR clocks
- REG_VALUE = 5 → 6 DDR clocks
- REG_VALUE = 6 → 6 DDR clocks

NOTE: Shadow registers are loaded on any frequency change or SidleReq/SidleAck transition at the point where the EMIF has put SDRAM into self-refresh mode.

CAUTION

All EMIF registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

Table 15-141 summarizes the EMIF register mapping.

15.3.6.2.1 EMIF Register Summary

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 15-141. EMIF Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	EMIF1 Physical Address	EMIF2 Physical Address

Table 15-144. EMIF_STATUS

Address Offset	0x0000 0004		
Physical Address	0x4C00 0004 0x4D00 0004	**Instance**	EMIF1 EMIF2
Description	SDRAM Status Register (STATUS)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BE	DUAL_CLK_MODE	FAST_INIT	RESERVED																					RDLVLGATETO	RDLVLTO	WRLVLTO	RESERVED	PHY_DLL_READY	RESERVED		

Bits	Field Name	Description	Type	Reset
31	BE	Big endian mode select for 8 and 16-bit devices, set to 1 for big endian or 0 for little endian operation. In current implementation, only 32-bit devices are supported - this bit is don't care.	R	0
30	DUAL_CLK_MODE	Dual Clock mode. Defines whether the EMIFi_L3_ICLK and EMIF_COREi clock are asynchronous. EMIFi_L3_ICLK and EMIF_COREi clock are asynchronous, if set to 1.	R	0
29	FAST_INIT	Fast Init. Defines whether the EMIF fast initialization mode has been enabled. Fast initialization is enabled if set to 1.	R	0
28:7	RESERVED	Reserved	R	0x00 0000
6	RDLVLGATETO	Read DQS Gate Training Timeout. Value of 1 indicates read DQS gate training has timed out because read DQS gate training done was not received from the PHY.	R	0
5	RDLVLTO	Read Data Eye Training Timeout. Value of 1 indicates read data eye training has timed out because read data eye training done was not received from the PHY.	R	0

Bits	Field Name	Description	Type	Reset
4	WRLVLTO	Write Leveling Timeout. Value of 1 indicates write leveling has timed out because write leveling done was not received from the PHY.	R	0
3	RESERVED		R	0
2	PHY_DLL_READY	DDR PHY Ready. The DDR PHY is ready for normal operation, if set to 1.	R	0
1:0	RESERVED	Reserved	R	0x0

Table 15-145. Register Call Summary for Register EMIF_STATUS

EMIF Controller

- EMIF Register Summary: [0]

Table 15-146. EMIF_SDRAM_CONFIG

Address Offset 0x0000 0008

Physical Address 0x4C00 0008 (EMIF1), 0x4D00 0008 (EMIF2) **Instance** EMIF1, EMIF2

Description SDRAM Config Register.
A write to this register will cause the EMIF to start the SDRAM initialization sequence. For LPDDR2, initialization is only re-started if it was not performed previously because EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS was a zero.
CAUTION: This register is loaded with values by control module at device reset.

Type RW

31 30 29	28 27 26	25 24	23	22	21 20	19 18	17 16	15 14	13 12 11 10	9 8	7 6 5 4	3 2	1 0
SDRAM_TYPE	IBANK_POS	DDR_TERM	DDR2_DDQS	DYN_ODT	DDR_DISABLE_DLL	SDRAM_DRIVE	CWL	NARROW_MODE	CL	ROWSIZE	IBANK	EBANK	PAGESIZE

Bits	Field Name	Description	Type	Reset
31:29	SDRAM_TYPE	SDRAM Type selection. This field is loaded from e-fuse. Set to 3 for DDR3 Set to 4 for LPDDR2 All other values are reserved.	RW	0x0
28:27	IBANK_POS	Internal bank position. See section Section 15.3.4.12, *SDRAM Address Mapping*.	RW	0x0
26:24	DDR_TERM	DDR3 termination resistor value. Set to 0 to disable termination. For DDR3, set to 1 for RZQ/4, set to 2 for RZQ/2, set to 3 for RZQ/6, set to 4 for RZQ/12, and set to 5 for RZQ/8. All other values are reserved.	RW	0x0
23	DDR2_DDQS	DDR2 differential DDQS enable. NOT SUPPORTED. Set to 1 for compatibility.	RW	0
22:21	DYN_ODT	DDR3 Dynamic ODT. NOT SUPPORTED. Set to 0 to turn off dynamic ODT.	RW	0x0
20	DDR_DISABLE_DLL	Disable DLL select. Set to 1 to disable DLL inside SDRAM.	RW	0
19:18	SDRAM_DRIVE	SDRAM drive strength.For DDR3, set to 0 for RZQ/6 and set to 1 for RZQ/7. All other values are reserved.	RW	0x0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
17:16	CWL	DDR3 CAS Write latency. Value of 0, 1, 2, and 3 (CAS write latency of 5, 6, 7, and 8) are supported. Use the lowest value supported for best performance. All other values are reserved.	RW	0x0
15:14	NARROW_MODE	SDRAM data bus width. Set to 0 for 32-bit and set to 1 for 16-bit. All other values are reserved. In the current implementation, only 32-bit devices are supported. Two DDR3 devices are used in parallel to make one 32-bit device.	RW	0x0
13:10	CL	CAS Latency (referred to as read latency (RL) in some SDRAM specs). The value of this field defines the CAS latency to be used when accessing connected SDRAM devices. Values of 3, 4, 5, 6, 7, and 8 (CAS latency of 3, 4, 5, 6, 7, and 8) are supported for LPDDR2-SDRAM. Values of 2, 4, 6, 8, 10, 12, and 14 (CAS latency of 5, 6, 7, 8, 9, 10, and 11) are supported for DDR3. All other values are reserved. The write latency (WL) is tied to the RL for the LPDDR2. See the LPDDR2 SDRAM standard. Also program the EMIF_DDR_PHY_CONTROL_1[4:0] READ_LATENCY	RW	0x0
9:7	ROWSIZE	Row Size. Defines the number of row address bits of connected SDRAM devices. Set to 0 for 9 row bits, Set to 1 for 10 row bits, Set to 2 for 11 row bits, Set to 3 for 12 row bits, Set to 4 for 13 row bits, Set to 5 for 14 row bits, Set to 6 for 15 row bits, Set to 7 for 16 row bits. This field is only used when EMIF_SDRAM_CONFIG[28:27] IBANK_POS field is set to 1, 2, or 3 or EBANK_POS field in EMIF_SDRAM_CONFIG_2 register is set to 1.	RW	0x0
6:4	IBANK	Internal Bank setup. Defines number of banks inside connected SDRAM devices. Set to 0 for 1 bank, Set to 1 for 2 banks, Set to 2 for 4 banks, Set to 3 for 8 banks. All other values are reserved.	RW	0x0
3	EBANK	External chip select setup. Defines whether SDRAM accesses will use 1 or 2 chip select lines. Set to 0 to use NCS0 only. Set to 1 to use NCS[1:0]. This bit will automatically be set to 0 if EMIF_SDRAM_CONFIG_2[30] CS1NVMEN field is set to 1.	RW	0
2:0	PAGESIZE	Page Size. Defines the internal page size of connected SDRAM devices. Set to 0 for 256-word page (8 column bits), Set to 1 for 512-word page (9 column bits), Set to 2 for 1024-word page (10 column bits), Set to 3 for 2048-word page (11 column bits). All other values are reserved.	RW	0x0

Table 15-150. EMIF_SDRAM_REFRESH_CONTROL

Address Offset	0x0000 0010		
Physical Address	0x4C00 0010 0x4D00 0010	**Instance**	EMIF1 EMIF2
Description	SDRAM Refresh Control Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INITREF_DIS	RESERVED	SRT	ASR	RESERVED	PASR			RESERVED								REFRESH_RATE															

Bits	Field Name	Description	Type	Reset
31	INITREF_DIS	Initialization and Refresh disable. When set to 1, EMIF will disable SDRAM initialization and refreshes, but will carry out SDRAM write/read transactions.	RW	0
30	RESERVED		R	0
29	SRT	DDR3 Self Refresh temperature range. Set to 0 for normal operating temperature range and set to 1 for extended operating temperature range when the ASR field is set to 0. This bit must be set to 0 if the ASR field is set to 1. A write to this field will cause the EMIF to start the SDRAM initialization sequence.	RW	0
28	ASR	DDR3 Auto Self Refresh enable. Set to 1 for auto Self Refresh enable. Set to 0 for manual Self Refresh reference indicated by the SRT field. A write to this field will cause the EMIF to start the SDRAM initialization sequence.	RW	0
27	RESERVED		R	0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
26:24	PASR	Partial Array Self Refresh. These bits get loaded into the Extended Mode Register of DDR3 during initialization. For DDR3, set to 0 for full array, set to 1 or 5 for 1/2 array, set to 2 or 6 for 1/4 array, set to 3 or 7 for 1/8 array, and set to 4 for 3/4 array to be refreshed. All other values are reserved. A write to this field will cause the EMIF to start the SDRAM initialization sequence.	RW	0x0
23:16	RESERVED		R	0x00
15:0	REFRESH_RATE	Refresh Rate. Value in this field is used to define the rate at which connected SDRAM devices will be refreshed. SDRAM refresh rate = REFRESH_RATE / EMIFi_PHY_FICLK. A 533-MHz DDR clock rate system that requires a 7.8 µs refresh rate would need 7.8 × 533 = 4157 or 0x103D value to be written. To avoid lock-up situations, the programmer must not program REFRESH_RATE < (6 × EMIF_SDRAM_TIMING_3[12:4] T_RFC).	RW	0x0000

Address Offset	0x0000 0098		
Physical Address	0x4C00 0098 0x4D00 0098	**Instance**	EMIF1 EMIF2
Description	Control register to force idle window time to generate a phy_dll_calib that can be used for updating PHY DLLs during voltage ramps. NOTE: Should always be loaded via the shadow register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												ACK_WAIT				RESERVED								DLL_CALIB_INTERVAL							

Bits	Field Name	Description	Type	Reset
31:20	RESERVED		R	0x000
19:16	ACK_WAIT	The ack_wait determines the required wait time after a phy_dll_calib is generated before another command can be sent. Value program is in terms of EMIF_COREi cycle count. **CAUTION:** 5 must be the minimum value ever programmed.	RW	0x9
15:9	RESERVED		R	0x00
8:0	DLL_CALIB_INTERVAL	This field determines the interval between phy_dll_calib generation. This value is multiplied by a precounter of 16 EMIF_COREi cycles. Program this field one less the value you are targeting; program 1 to achieve interval of 2 (minimum interval supported). Programming zero turns off function. Note the final intervals between dll_calib generation is also a function of ACK_WAIT. Final periodic interval is calculated by: ((DLL_CALIB_INTERVAL + 1) × 16) + ACK_WAIT	RW	0x000

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Reserved	RW	0x0
27	RDLVL_MASK	Writing a 1 to this field will mask read data eye training during full leveling command, plus drives reg_phy_use_rd_data_eye_level control low to allow user to use programmed ratio values. Incremental training needs to be disabled using incremental training registers.	RW	0
26	RDLVLGATE_MASK	Writing a 1 to this field will mask dqs gate training during full leveling command, plus drives reg_phy_use_rd_dqs_level control low to allow user to use programmed ratio values. Incremental training needs to be disabled using incremental training registers.	RW	0
25	WRLVL_MASK	Writing a 1 to this field will mask write leveling training during full leveling command, plus drives reg_phy_use_wr_level control low to allow user to use programmed ratio values. Incremental training needs to be disabled using incremental training registers.	RW	0
24:22	RESERVED	Reserved	RW	0x0
21	PHY_HALF_DELAYS	Adjust slave delay line delays to support 2× mode 1: 2× mode (MDLL clock is half the rate of PHY) - OPP_NOM 0: 1× mode (MDLL clock rate is same as PHY) - OPP_BOOT	RW	0
20	PHY_CLK_STALL_LEVEL	Enable variable idle value for delay lines. Enable during normal operations to avoid differential aging in the delay lines.	RW	0
19	PHY_DIS_CALIB_RST	Disable the dll_calib (internally generated) signal from resetting the Read Capture FIFO pointers and portions of data PHYs. Debug only. Note: dll_calib is generated by 1. EMIF_MISC_REG[0] DLL_CALIB_OS set to 1,or 2. by the PHY when it detects that the clock frequency variation has exceeded the bounds set by PHY_DLL_LOCK_DIFF or 3. periodically throughout the leveling process.	RW	0
18	PHY_INVERT_CLKOUT	Inverts the polarity of DRAM clock. This bit must be set to 0 when in LDDDR2 mode. 0: core clock is passed on to DRAM 1: inverted core clock is passed on to DRAM	RW	0
17:10	PHY_DLL_LOCK_DIFF	The maximum number of delay line taps variation while maintaining the master DLL lock. When the PHY is in locked state and the variation on the clock exceeds the variation indicated by this field, the lock signal is de-asserted and a dll_calib signal is generated. To prevent the dll_calib signal from being asserted in the middle of traffic when the clock jitter exceeds the variation, this register needs to be set to a value which will ensure that the lock will not be lost. Recommended value is 16.	RW	0x02

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
9	PHY_FAST_DLL_LOCK	Controls master DLL to lock fast or average logic must be part of locking process. Set to 1 before OPP transition commences, and set back to 0 after OPP transition completes. 1: MDLL lock is asserted based on single sample 0: MDLL lock is asserted based on average of 16 samples.	RW	0
8:5	RESERVED	Reserved	RW	0x00
4:0	READ_LATENCY	This field defines the read latency for the read data from SDRAM in number of DDR clock cycles. This field is used by the EMIF as well as the PHY. READ_LATENCY = RL + reg_phy_rdc_we_to_re -1. EMIF uses above equation to calculate reg_phy_rdc_we_to_re and forward it to the PHY. For DDR3, the true RL is used, not the decoded value. See JEDEC spec. The write latency (WL) is tied to the RL for the LPDDR2. See the LPDDR2 SDRAM standard.	RW	0x01E

15.4 General-Purpose Memory Controller

15.4.1 GPMC Overview

The general-purpose memory controller (GPMC) is a unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in nonmultiplexed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

The GPMC is also introduced in Section 15.1, *Memory Subsystem Overview*.

15.4.2 GPMC Environment

This section describes the GPMC application fields from an environment point of view (external connections). It describes GPMC connectivity options, and gives three possible interfaces.

15.4.2.1 GPMC Modes

This section shows three GPMC external connections options:

- Figure 15-51 shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol uses fewer address pins) external memory device.
- Figure 15-52 shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device .
- Figure 15-53 shows a connection between the GPMC and a 8-bit NAND device.

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit-wide device interfacing (for multiplexed and nonmultiplexed protocol). Hence, an 8-bit device must be connected to the D[7:0]/gpmc_ad[7:0] data bus (rather than D[15:8]/gpmc_ad[15:8]) of the GPMC controller. This limits the use of 8-bit-wide device interfacing to byte-alias access.

15.4.2.2 GPMC Signals

Table 15-332 lists the GPMC subsystem input/output (I/O) pins.

Table 15-332. GPMC I/O Description

Pin Name	Device Signal	I/O[1]	Description
A[26:17]	gpmc_a[25:16]	O	Address
A[16:1]/D[15:0]	gpmc_ad[15:0]	I/O	Multiplexed address/data
nCS[7:0]	gpmc_ncs[7:0]	O	Chip-selects (active low)
CLK	gpmc_clk	O[2]	Clock generated for the external memory or device
nADV/ALE	gpmc_nadv_ale	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
nOE/nRE	gpmc_noe_nre	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
nWE	gpmc_nwe	O	Write enable (active low)
nBE0/CLE	gpmc_nbe0_cle	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
nBE1	gpmc_nbe1	O	Upper-byte enable (active low).
nWP	gpmc_nwp	O	Write protect (active low)
WAIT[2:0]	gpmc_wait[2:0]	I	External wait signal for NOR and NAND protocol memories. The wait signals can be mapped on any of the chip-select.

(1) I = Input; O = Output

(2) This output signal is also used as retiming input. During synchronous operation, the INPUTENABLE bit of the CONTROL_CORE_PAD0_GPMC_NWP_PAD1_GPMC_CLK register must be set to 1.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*.

Table 15-333 shows the use of address and data GPMC controller pins based on the type of external device.

Table 15-333. GPMC Pin Multiplexing Options

GPMC Pin	Multiplexed Address Data 16-Bit Device	Nonmultiplexed Address Data 16-Bit Device With LIMITED-ADDRESS Bit Enabled	16-Bit NAND Device	8-Bit NAND Device

gpmc_a[24]	A25	A9	Not used	Not used
gpmc_a[23]	A24	A8	Not used	Not used
gpmc_a[22]	A23	A7	Not used	Not used
gpmc_a[21]	A22	A6	Not used	Not used
gpmc_a[20]	A21	A5	Not used	Not used
gpmc_a[19]	A20	A4	Not used	Not used
gpmc_a[18]	A19	A3	Not used	Not used
gpmc_a[17]	A18	A2	Not used	Not used
gpmc_a[16]	A17	A1	Not used	Not used
gpmc_ad[15]	A16/D15	D15	D15	Not used
gpmc_ad[14]	A15/D14	D14	D14	Not used
gpmc_ad[13]	A14/D13	D13	D13	Not used
gpmc_ad[12]	A13/D12	D12	D12	Not used
gpmc_ad[11]	A12/D11	D11	D11	Not used
gpmc_ad[10]	A11/D10	D10	D10	Not used
gpmc_ad[9]	A10/D9	D9	D9	Not used
gpmc_ad[8]	A9/D8	D8	D8	Not used
gpmc_ad[7]	A8/D7	D7	D7	D7
gpmc_ad[6]	A7/D6	D6	D6	D6
gpmc_ad[5]	A6/D5	D5	D5	D5
gpmc_ad[4]	A5/D4	D4	D4	D4
gpmc_ad[3]	A4/D3	D3	D3	D3
gpmc_ad[2]	A3/D2	D2	D2	D2
gpmc_ad[1]	A2/D1	D1	D1	D1
gpmc_ad[0]	A1/D0	D0	D0	D0

When using nonmultiplexed memories, it is recommended to enable the GPMC_CONFIG[1] LIMITEDADDRESS bit. This bit forces A[26:11] to 1 on the GPMC I/O side. Thus, only 2 KiB of memory address space is accessible, regardless of the memory size.

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit-wide devices:

- The NOR flash memory controller still supports nonmultiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (where i = 0 to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

NOTE: The numbering for A (address) starts from 1 instead of 0, such as D (data), because the A0 signal is handled within the GPMC but is not driven to any pad. The signal is relevant only to 8-bit accesses and this configuration is not recommended. If such a memory or device is connected, only every second word in the memory is accessible; that is, each 16-bit-aligned 8-bit word is mapped, but not the non-16-bit aligned ones. Any access to a nonaligned word results in accessing the associated aligned word, at address A1 instead of address A.

15.4.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- No STANDBY hardware handshake
- No wake-up request
- One system direct memory access (sDMA) request
- One interrupt request to the microprocessor unit (MPU) interrupt controller (INTC) and to the DSP subsystem
- One clock for functional and interface domains

Figure 15-54 shows GPMC integration.

15.4.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait-state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

15.4.4.1 GPMC Block Diagram

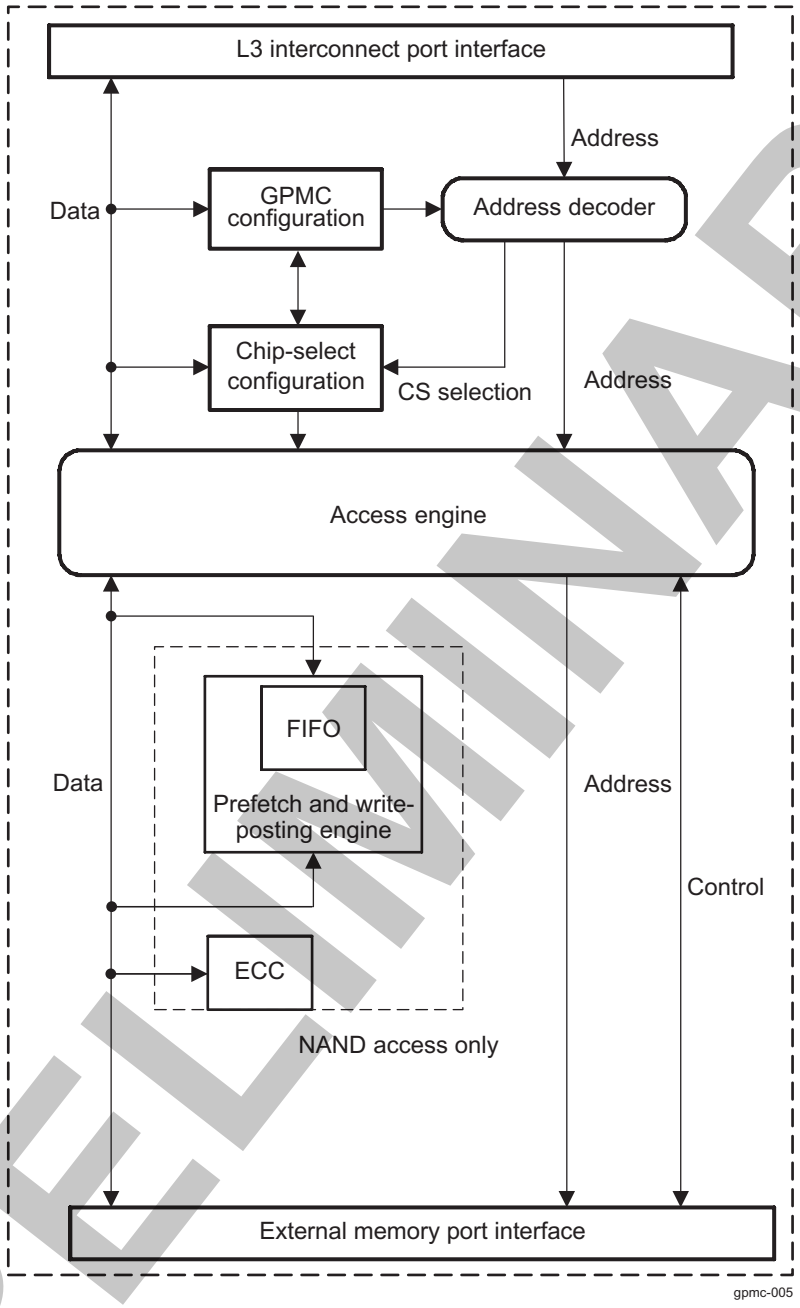
Figure 15-55 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 15-55. GPMC Block Diagram



The GPMC can access various external devices through the L3_MAIN Interconnect. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC can generate the timing of all control signals depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate control signal timing for the device type.

15.4.4.2 GPMC Clock Configuration

Table 15-337 describes the GPMC clocks.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 15-337. GPMC Clocks

Signal	I/O[1]	Description
GPMC_FCLK	I	Functional and interface clock
gpmc_clk	O	External clock provided to synchronous external memory devices

(1) I = Input; O = Output

The gpmc_clk is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in Table 15-335. The gpmc_clk is configured using the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where i = 0 to 7), as shown in Table 15-338.

Table 15-338. gpmc_clk Configuration

Source Clock	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	gpmc_clk Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

15.4.4.3 GPMC Software Reset

The GPMC can be reset by software through the GPMC_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The GPMC_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. Software must ensure that the software reset completes before performing GPMC operations.

15.4.4.4 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

Table 15-339 describes the power-management features available for the GPMC module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions, see Section 3.1.1.1, *Clock Management*, in Section 3.1.1, *Power, Reset, and Clock Management*.
- For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.6, *Clock Management Functional Description*, in Section 3.1.1, *Power, Reset, and Clock Management*.

Table 15-339. GPMC Local Power-Management Features

Feature	Registers	Description
Clock autogating	GPMC_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave idle modes	GPMC_SYSCONFIG[4:3] SIDLEMODE	Force-idle, no-idle and smart-idle wake-up modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

15.4.4.5 GPMC Interrupt Requests

The GPMC generates one interrupt request (see Figure 15-54).

Table 15-340 lists the event flags, and their mask, that can cause module interrupts.

Table 15-340. GPMC Interrupt Events

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[10] WAIT2EDGE DETECTIONSTATUS	GPMC_IRQENABLE[10] WAIT2EDGE DETECTIONENABLE	Edge	Wait2 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait2 signal. The rising or falling edge detection of Wait2 is selected through the GPMC_CONFIG[10] WAIT2PINPOLARITY bit.
GPMC_IRQSTATUS[9] WAIT1EDGE DETECTIONSTATUS	GPMC_IRQENABLE[9] WAIT1EDGE DETECTIONENABLE	Edge	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait1 signal. The rising or falling edge detection of Wait1 is selected through the GPMC_CONFIG[9] WAIT1PINPOLARITY bit.
GPMC_IRQSTATUS[8] WAIT0EDGE DETECTIONSTATUS	GPMC_IRQENABLE[8] WAIT0EDGE DETECTIONENABLE	Edge	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait0 signal. The rising or falling edge detection of Wait0 is selected through the GPMC_CONFIG[8] WAIT0PINPOLARITY bit.
GPMC_IRQSTATUS[1] TERMINAL COUNTSTATUS	GPMC_IRQENABLE[1] TERMINAL COUNTENABLE	Level	Terminal count event: Triggered on prefetch process completion; that is, when the number of currently remaining data to be requested reaches 0
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	FIFO event interrupt: Indicates available FIFO levels for write-posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1[2] DMAMODE must be set to 0.

15.4.4.6 GPMC DMA Requests

The GPMC generates one DMA event (see Figure 15-54).

15.4.4.7 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including a 16 × 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-, 16-, or 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32, and 16 × 32, with the burst base address aligned on the total burst size, are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line for specific event control.

It is recommended to program the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field according to the page length of the effective attached device and to enable the GPMC_CONFIG1_i[31] WRAPBURST bit if the attached device supports wrapping burst.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

It is possible, however, to emulate wrapping burst on a nonwrapping memory by providing relevant addresses within the page or by splitting transactions. Bursts larger than the memory page length are chopped into multiple burst transactions. Because of the alignment requirements, a page boundary is never crossed.

15.4.4.8 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-nonmultiplexed memories or devices is supported with a limited address range of 2KiB.

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- When the GPMC_CONFIG[1] LIMITEDADDRESS bit is set to 1, A26–A11 are not modified during an external memory access. This limits the memory address space to 2KiB, regardless of the memory size.
- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit-wide NOR devices do not use GPMC I/O: gpmc_ad[15:8] for data (they are used for address if needed).
- 16-bit-wide NAND devices do not use GPMC I/O: gpmc_a[25:16].
- 8-bit-wide NAND devices do not use GPMC I/O: gpmc_a[25:16] and GPMC I/O: gpmc_ad[15:8].

CAUTION

Before accessing a chip-select configured with a nonmultiplexed protocol, set the LIMITEDADDRESS bit control.

15.4.4.8.1 GPMC I/O Configuration Setting

NOTE: In this section and the following sections, the i in GPMC_CONFIGx_i stands for the GPMC chip-select i, where i = 0 to 7.

To select a NAND device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b10
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b00

To select an address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b01

To select an address/data-nonmultiplexed device (limited to a 2-KiB address range), program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b00
- GPMC_CONFIG[1] LIMITEDADDRESS = 1

NOTE: The GPMC_CONFIG[1] LIMITEDADDRESS bit applies only to address/data-nonmultiplexed devices; it has no effect on other device types (NAND, address/data-multiplexed).

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

15.4.4.8.2 GPMC CS0 Default Configuration at Device Reset

To ensure a correct, fast external boot (see Section 28.3.6, *Fast External Booting*, in Section 28.1, *Initialization*) with a GPMC access on device reset, several pins are sampled:

- The sys_boot[3:0] pins (device boundary) define the sequence of interfaces and devices to use for booting. They are sampled by the control module at reset and used later by the device ROM code. For more information, see Section 28.2.4, *Boot Configuration*, in Section 28.1, *Initialization,* .
- Additional pins are used to configure reset values in the GPMC_CONFIG1_i register (where i = 0) as explained in the following and in Table 15-341:
  - The *bootdevicesize* input pin (at the GPMC boundary) defines the size of the attached device on chip-select 0 (CS0) and is used to configure the GPMC_CONFIG1_i[13:12] DEVICESIZE bit field (where i = 0). The BOOT_DEVICE_TYPE signal is propagated from the device control module. Its value is fixed for the device at 0x1 at device reset, which means that only 16-bit memories are supported for booting.
  - The *cs0muxdevice* input pin (at the GPMC boundary) selects whether or not the device attached to CS0 is an address/data-multiplexed device. The input pin is used to configure the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (where i = 0). The CS0_MUX_DEVICE signal is propagated from the SCM. Its value is fixed for the device at 0x2 at device reset, which means only address/data-multiplexed memories are supported for booting (that is, in a standalone way from memories connected to CS0).
  - The *bootwaiten* input pin (at the GPMC boundary) enables the monitoring on CS0 of the wait pin at device reset release time for read accesses. The input pin is used to configure the GPMC_CONFIG1_i[22] WAITREADMONITORING bit (where i = 0). The BOOT_WAIT_ENABLE signal is propagated from the system control module (SCM). When sys_boot[5:0] = 0b11 1111, the BOOT_WAIT_ENABLE signal is activated, which causes the wait pin to be monitored for read accesses.
  - The *bootwaitselect* input pin selects the WAIT signal at device reset release time between the WAIT0, WAIT1, and WAIT2 input pins. At device reset release time, these three pins have different polarity.

Table 15-341. Boot Control Interface Input Signals Description

Signal Name	Width	Description
bootdevicesize	2	Size of the device attached on CS0 0b00: 8-bit 0b01: 16-bit 0b10: Reserved 0b11: Reserved
cs0muxdevice	2	Multiplexing mode of the device on CS0 0b00: Nonmultiplexed device on CS0 0b01: AAD-multiplexed device on CS0 (address-address-data) 0b10: Address/data-multiplexed device on CS0 0b11: Reserved
bootwaiten	1	Wait monitoring on CS0 at device reset release time for read accesses 0: Wait pin is not monitored 1: Wait pin is monitored
bootwaitselect	1	Selection of the wait pin 0: WAIT0 input pin 1: WAIT1 input pin 2: WAIT2 input pin

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. For more information, see Section 28.3.7, *Memory Booting*, and Section 28.3.8 , *Image Format*, in Section 28.1, *Initialization*. This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed 2-KiB address range device attached to CS0

At reset time, the device can boot from the internal ROM.

The reset values of the timing control parameters are defined to cope with direct boot on address and data-multiplexed NOR flash devices, nonmultiplexed NOR flash devices, or any asynchronous device with large timing margins, assuming a low GPMC_FCLK frequency (for example, 19.2 MHz) at boot time.

For a multiplexed access, the address 16 low-order bits are presented onto gpmc_ad[15:0], while the high-order bits are presented onto gpmc_a[26:16]. If the external chip interface to the memories uses a 16-bit data bus, the high-order address bits are sampled on the address bus.

The reset values of timing parameters used at boot time are:

- CSONTIME = 1
- CSRDOFFTIME = 16
- ADVONTIME = 4
- ADVRDOFFTIME = 5
- OEONTIME = 6
- OEOFFTIME = 16
- RDACCESSTIME = 15
- RDCYCLETIME = 17

For an AAD-multiplexed access, all address bits are passed onto the data bus using two nADV rising edges. The first rising edge latches the address most-significant bit (MSB) down to bit 17, while the second rising edge latches address bits 16 down to 1. This configuration is only used for 16-bit memories.

The reset values of these timing parameters used at boot time are:

- ADVAADMUXONTIME = 1
- ADVAADMUXRDOFFTIME = 2
- OEAADMUXONTIME = 1
- OEAADMUXRDOFFTIME = 3

15.4.4.9 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file must be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). Section 15.4.7,*GPMC Register Manual*, provides the GPMC register locations. For the map of GPMC memory locations, see Section 2.2 , *Memory Mapping*.

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

15.4.4.9.1 Chip-Select Base Address and Region Size

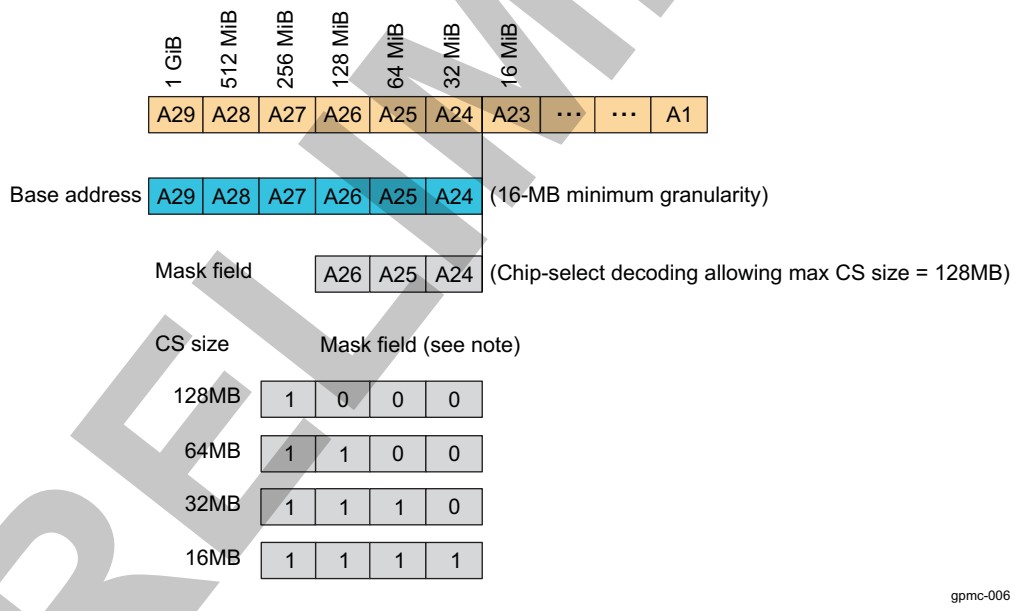
Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 512-MiB contiguous address space. For more information, see Section 2.2, *Memory Mapping*.

The GPMC 512-MiB address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable chip-select size. The chip-select size is programmable from 16MiB to 128MiB (must be a power-of-two) and is defined by the mask field. Attached memory smaller than the programmed chip-select region size is accessed through the entire chip-select region (aliasing).

Each chip-select has a 6-bit base address encoding and 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-two address value. During access decoding, the value of the register base address is used to compare the address with the address bit line mapping, as shown in Figure 15-56 (with A0 as the device system byte-address line). The base address is programmed through the GPMC_CONFIG7_i[5:0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The value of the register mask must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11:8] MASKADDRESS bit field.

Figure 15-56. Chip-Select Address Mapping and Decoding Mask



Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC_CONFIG7_i[6] CSVALID bit (where i stands for the GPMC chip-select value, 0 to 7). In addition, a chip-select configuration can be disabled only if there is no ongoing access to that chip-select. This requires monitoring the activity of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of overlapping chip-selects, an error is generated and no access occurs on either chip-select.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

CS0 is the only chip-select region enabled after a power up or GPMC reset.

CAUTION

Although the GPMC interface can drive up to four chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers to allow the slowest device to maintain the total load on the lines.

15.4.4.9.2 Access Protocol

15.4.4.9.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC_CONFIG1_i[11:10] DEVICETYPE parameter (where i = 0 to 7) for:

- Random-access synchronous or asynchronous memory, such as NOR flash and SRAM
- NAND flash asynchronous devices

NOTE: For more information about the NAND flash GPMC basic programming model and NAND support, see Section 15.4.4.13, *NAND Device Basic Programming Model*, and Section 15.4.4.13.1, *NAND Memory Device in Byte or Word16 Stream Mode*.

15.4.4.9.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC_CONFIG1_i[13:12] DEVICESIZE bit field (where i = 0 to 7) to interface with a 16- or 8-bit-wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to the external device data-bus width and little-endian data organization.

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit-wide device interfacing (for multiplexed and nonmultiplexed protocols). It limits the use of 8-bit-wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8- or 16-bit-wide devices).

15.4.4.9.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (where i = 0 to 7). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See Section 15.4.3, *GPMC Integration*.

NOTE: This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data-multiplexing protocol. See Section 15.4.4.13, *NAND Device Basic Programming Model*.

15.4.4.9.3 External Signals

15.4.4.9.3.1 Wait Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled using only the GPMC internal RDACCESSTIME, WRACCESSTIME, and PAGEBURSTACCESSTIME wait-state generator.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The GPMC features three input wait pins: gpmc_wait2, gpmc_wait1, and gpmc_wait0. These pins allow control of external devices with different wait pin polarity. They also allow the overlap of wait pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC_CONFIG1_i[17:16] WAITPINSELECT bit field (where i = 0 to 7) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When a wait pin is inactive, data is valid.

The GPMC access engine can be configured per chip-select to monitor or not the wait pin of the external memory device, based on the access type: read or write.

- The GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether or not the wait pin must be monitored during read accesses.
- The GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether or not the wait pin must be monitored during write accesses.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC_CONFIG1_i[29] READTYPE and GPMC_CONFIG1_i[27] WRITETYPE bits).

15.4.4.9.3.1.1 Wait Monitoring During Asynchronous Read Access

When wait pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a wait invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait monitoring pipelining is also applicable to multiple accesses (access within a page).

- Wait monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME bit field (where i = 0 to 7).

PRELIMINARY

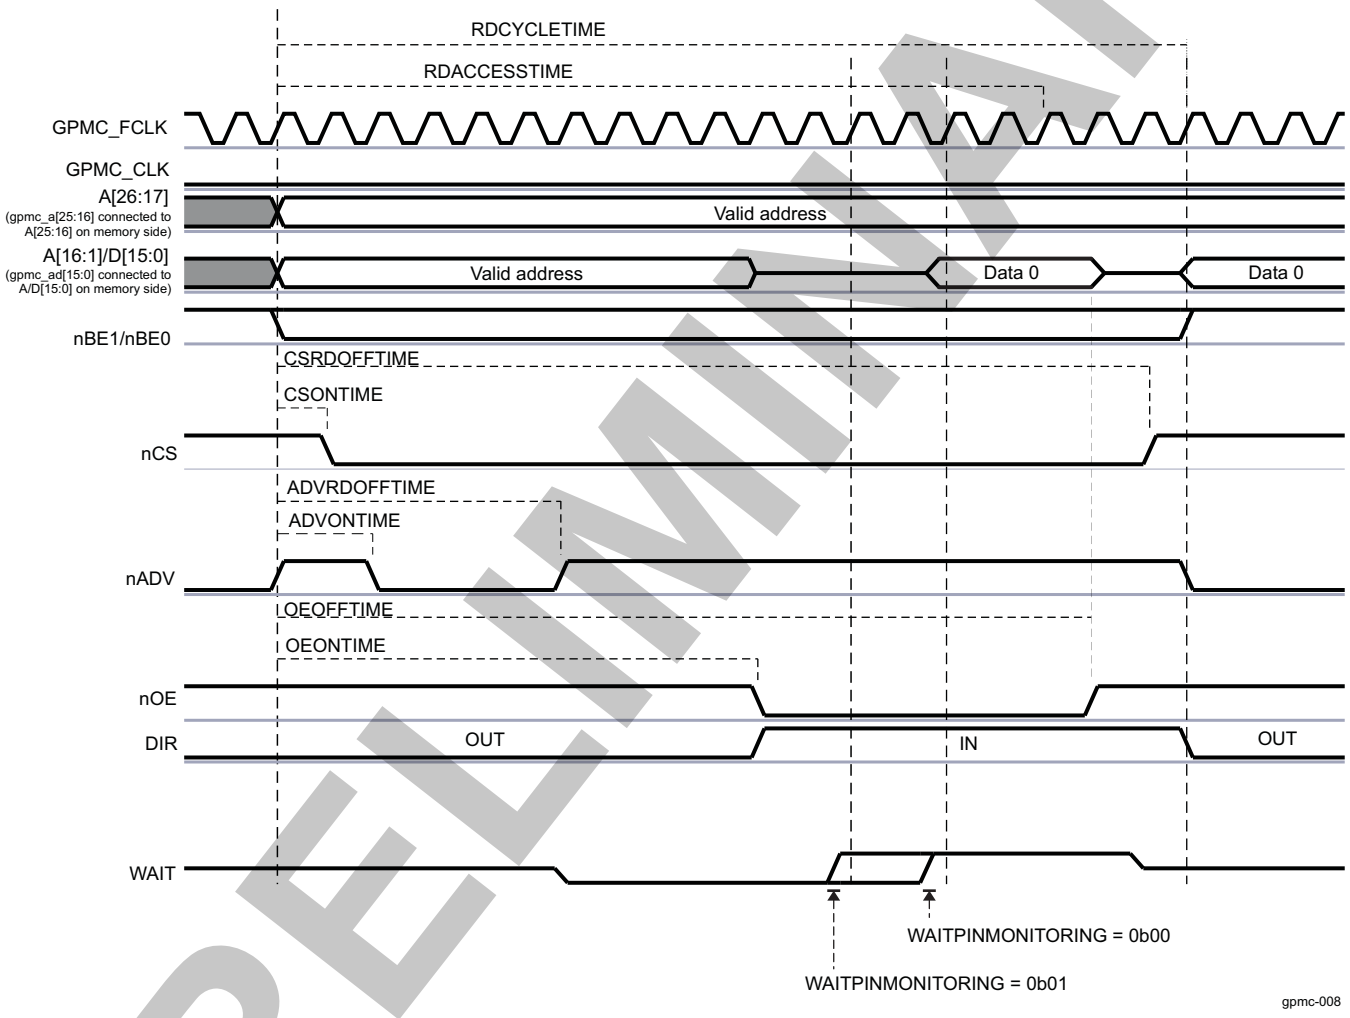
Copyright © 2013, Texas Instruments Incorporated

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, because GPMCFCLKDIVIDER is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 15-57 shows wait behavior during an asynchronous single read access.

Figure 15-57. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)



NOTE: The WAIT signal is active low. GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0b00, or 0b01.

15.4.4.9.3.1.2 Wait Monitoring During Asynchronous Write Access

When wait pin monitoring is enabled for write accesses (GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 0x1), the wait invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- Wait monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.

- Wait monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME bit field (where i = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, because the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

15.4.4.9.3.1.3 Wait Monitoring During Synchronous Read Access

During synchronous accesses with wait pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle in which it is captured. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle to which it applies. This pipelining is applicable to the entire burst access and to all data phases in the burst access. This wait pipelining depth is programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME bit field (where i = 0 to 7), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait pin monitoring is enabled (the GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state detection.

Depending on the programmed value of WAITMONITORINGTIME, the wait pin must be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the WAIT-INACTIVE state. The wait pipelining-depth programming applies to the whole burst access.

- Wait monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), wait monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), wait monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 15-58 shows wait behavior during a synchronous read burst access.

PRELIMINARY

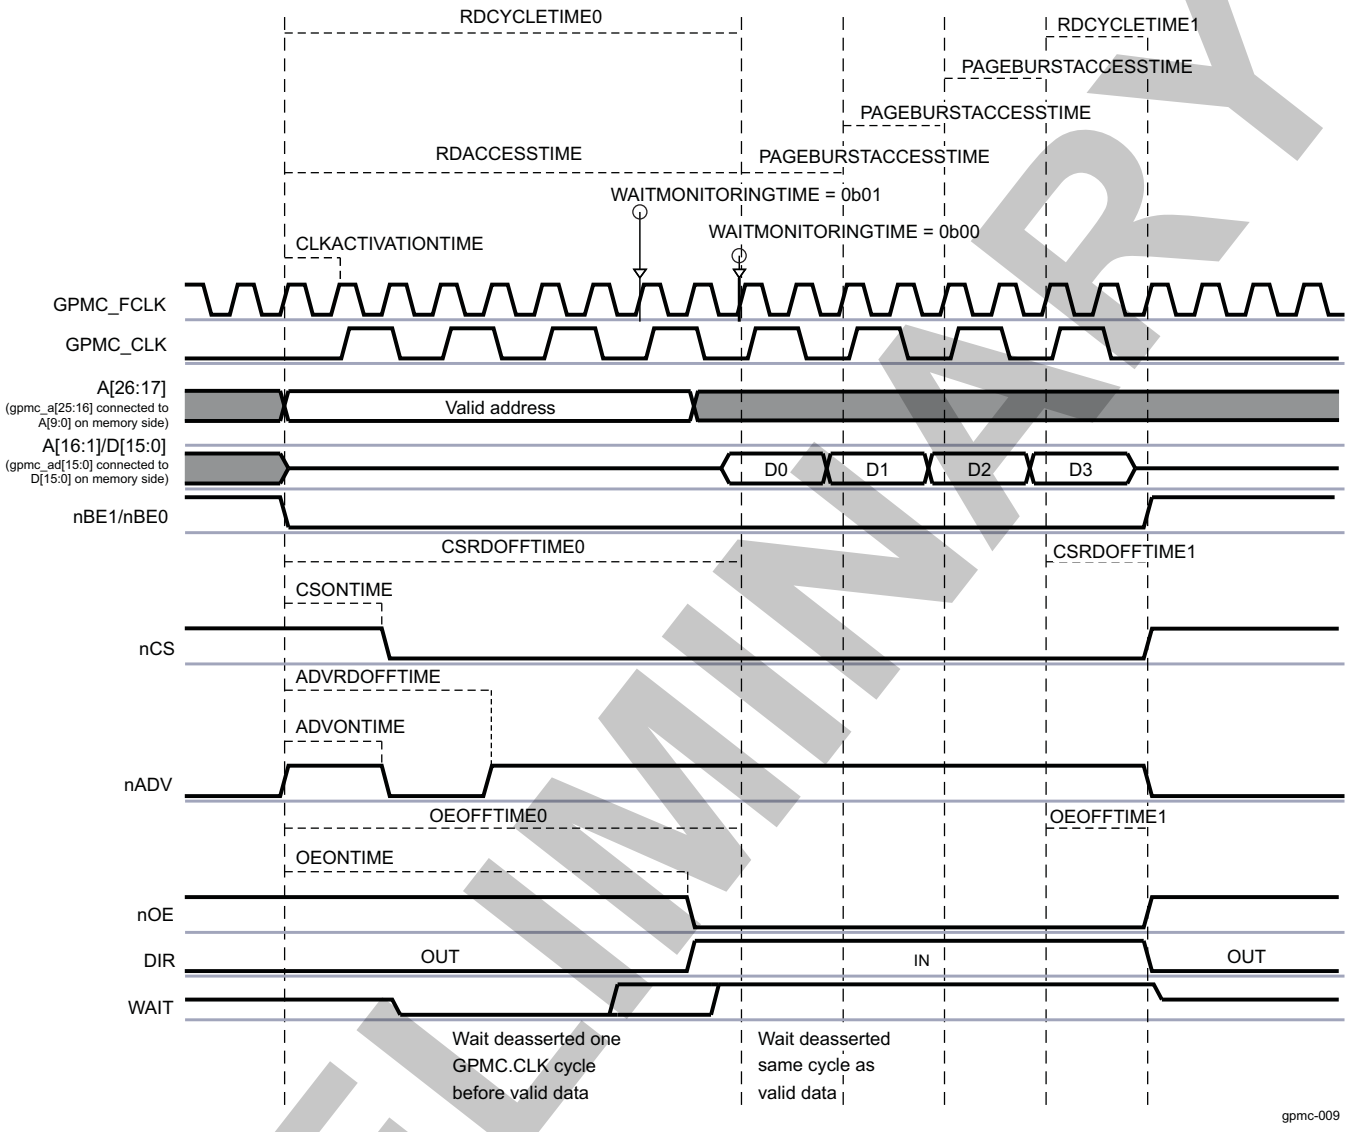
Figure 15-58. Wait Behavior During a Synchronous Read Burst Access



NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

15.4.4.9.3.1.4 Wait Monitoring During Synchronous Write Access

During synchronous accesses with wait pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait pin monitoring can be used in combination with WRACCESSTIME to delay the GPMC_CLK capture edge of the effective memory device.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Wait-monitoring pipelining definition applies to whole burst accesses:

- Wait monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as active indicates that the data

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.

- Wait monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

NOTE: Wait monitoring is supported for all configurations except GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0x0 (where i = 0 to 7) for write bursts with a clock divider of 1 or 2 (the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field is equal to 0x0 or 0x1, respectively).

15.4.4.9.3.1.5 Wait With NAND Device

For information about the use of the wait pin for communication with a NAND flash external device, see Section 15.4.4.13.2, *NAND Device-Ready Pin*.

15.4.4.9.3.1.6 Idle Cycle Control Between Successive Accesses

15.4.4.9.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE deassertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE deassertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC_CONFIG6_i[3:0] BUSTURNAROUND bit field (where i = 0 to 7).

After a read access to a chip-select with a nonzero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (the same or different chip-select from which the data was read)
- A read access to a different chip-select than the chip-select from which the data was read access
- A read or write access to a chip-select associated with an address/data-multiplexed device

NOTE: Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus does not have enough time to go into high-impedance even though it can be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC_CONFIG6_i[3:0] CYCLE2CYCLEDELAY bi field delays. BUSTURNAROUND is a timing parameter for the ending chip-select access, while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access (see Figure 15-59 through Figure 15-61).

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but it also affects all accesses of this specific chip-select.

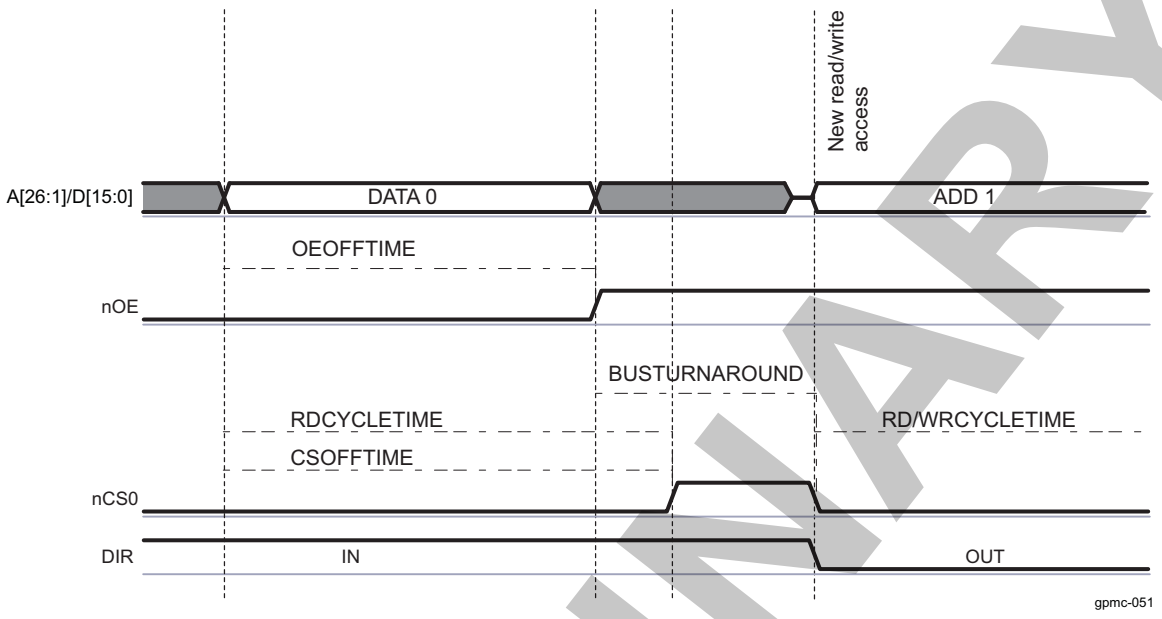
Figure 15-61. Read-to-Read/Write for a Address-Data or AAD-Multiplexed Device, on Same Chip-Select, With Bus Turnaround



15.4.4.9.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit (where i = 0 to 7) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY bit field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

15.4.4.9.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and deassertion timing parameters and on the device timing parameters, the assertion times of some control signals may overlap between the successive accesses to a different chip-select. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

If the GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN bit is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

NOTE: CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN must be set in the GPMC_CONFIG6_i registers to get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select, respectively.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. The BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, because bus turnaround does not apply to all access types. For more information about bus turnaround, see Section 15.4.4.9.3.1.6.1, *Bus Turnaround (BUSTURNAROUND)*.

Table 15-342 describes the configuration required for idle cycle insertion.

Table 15-342. Idle Cycle Insertion Configuration

1st Access Type	BUSTURNAROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2CYCLESAMECSEN Parameter	CYCLE2CYCLEDIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

15.4.4.9.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select value, 0 to 7). Increasing all access timing parameters allows support of slow devices.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

15.4.4.9.3.2 gpmc_io_dir Pin

The gpmc_io_dir pin is used to control I/O direction on the GPMC data bus gpmc_ad[15:0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the device, if required.

The gpmc_io_dir pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the gpmc_io_dir pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the gpmc_io_dir pin goes from OUT-to-IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled:
  - The gpmc_io_dir pin goes from IN-to-OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled:
  - After an asynchronous read access, the gpmc_io_dir pin goes from IN-to-OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the gpmc_io_dir pin goes from IN-to-OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the gpmc_io_dir pin is OUT (see Section 15.4.4.10.10, *Bus Keeping Support*).

In nonmultiplexed devices, the gpmc_io_dir pin stays IN between two successive read accesses to prevent unnecessary toggling (nonmultiplexed 16-bit-wide device support is limited to 2KiB).

15.4.4.9.3.3 Reset

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see Section 3.1.1, *Power, Reset, and Clock Management*.

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during device warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

15.4.4.9.3.4 Write Protect Signal (nWP)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory.

The gpmc_nwp output pin value is controlled through the GPMC_CONFIG[4] WRITEPROTECT bit, which is common to all chip-selects.

15.4.4.9.3.5 Byte Enable (nBE1/nBE0)

Byte enable signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

15.4.4.9.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC_ERR_ADDRESS register. The GPMC keeps only the first error abort information until the GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC_ERR_TYPE[0] ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KiB.

- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the L3 interconnect interface.
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC_TIMEOUT_CONTROL register and enabled with the GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at interconnect level.

15.4.4.10 Timing Setting

The GPMC offers maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information about GPMC_CLK and GPMC_FCLK see Section 15.4.4.10.6, *GPMC_CLK*.

NOTE: In the following sections, the start access time refers to the time at which the access begins.

15.4.4.10.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC_CONFIG5_i[4:0] RDCYCLETIME and GPMC_CONFIG5_i[12:8] WRCYCLETIME bit fields (where i = 0 to 7) define the address bus and byte-enable valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle. The RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

When RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (nCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

NOTE: All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles.

If no inactive cycles are required between successive accesses to the same chip-select or a different chip-select (GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0 or GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0, where i = 0 to 7), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses (that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1), the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

15.4.4.10.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC_CONFIG2_i[3:0] CSONTIME bit field (where i = 0 to 7) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC_CONFIG2_i[12:8] CSRDOFFTIME (read access) and GPMC_CONFIG2_i[20:16] CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

The CSONTIME, CSRDOFFTIME, and CSWROFFTIME parameters apply to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte-enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte-enable hold time after chip-select deassertion.

nCS signal transitions, as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME, can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but it can also be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters that control nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

15.4.4.10.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The GPMC_CONFIG3_i[3:0] ADVONTIME field (where i = 0 to 7) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME (read access) and GPMC_CONFIG3_i[20:16] ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte-enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte-enable valid hold time control after nADV/ALE deassertion. ADVRDOFFTIME and ADVWROFFTIME apply to synchronous and asynchronous modes.

The nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME, GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME, and GPMC_CONFIG3_i[30:28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. The user must ensure that ADVAADMUXxxOFFTIME is programmed to a value less than or equal to ADVxxOFFTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV pulse is needed between the two AAD-multiplexed address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

Copyright © 2013, Texas Instruments Incorporated

For more information about the use of ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME and ADVAADMUXWROFFTIME for command latch enable (CLE) and address latch enable (ALE) use for a NAND flash interface, see Section 15.4.4.13, *NAND Access Description*.

15.4.4.10.4 nOE/nRE: Output Enable/Read Enable Signal Control Assertion/Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The GPMC_CONFIG4_i[3:0] OEONTIME bit field (where i = 0 to 7) defines the nOE/nRE signal assertion time relative to start access time. It applies only to read accesses.

The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field defines the nOE/nRE signal deassertion time relative to start access time. It applies only to read accesses. nOE/nRE is not asserted during a write cycle.

The OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME parameters apply to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte-enable valid hold time control after nOE/nRE assertion.

The OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. The user mut ensure that OEAADMUXOFFTIME is programmed to a value less than OEONTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME must never be equal to OEONTIME because the AAD-multiplexed protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nOE/RE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than the nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

NOTE: When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

15.4.4.10.5 nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i[19:16] WEONTIME bit field (where i = 0 to 7) defines the nWE signal-assertion time relative to start access time. The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field defines the nWE signal-deassertion time relative to start access time. These bit fields apply only to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte-enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte-enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

15.4.4.10.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where i = 0 to 7), with a guaranteed 50-percent duty cycle.
- The GPMC_CLK clock is activated only when the access in progress is defined as synchronous (read or write access).
- The GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field (where i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

CAUTION

When the cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the required 50-percent duty cycle, the user must extend the RDCYCLETIME or WRCYCLETIME value.

NOTE: To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

15.4.4.10.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field (where i = 0 to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of the control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by a half-GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

15.4.4.10.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read/write access time durations can be programmed independently through the GPMC_CONFIG5_i[20:16] RDACCESSTIME and GPMC_CONFIG6_i[28:24] WRACCESSTIME bit fields (where i = 0 to 7). This allows nOE and GPMC data-capture timing parameters to be independent of nWE and memory device data capture timing parameters. The RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

15.4.4.10.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field (where i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK, which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field must be greater than RDACCESSTIME to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in asynchronous and synchronous modes. For more information about wait monitoring, see Section 15.4.4.9.3.1, *Wait Pin Monitoring Control*.

15.4.4.10.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a wait invalid timing window and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For more information about wait monitoring, see Section 15.4.4.9.3.1, *Wait Pin Monitoring Control*.

In synchronous write mode , for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data-capture GPMC_CLK edge for a synchronous write access. For more information about wait monitoring, see Section 15.4.4.9.3.1, *Wait Pin Monitoring Control*.

15.4.4.10.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

The GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field (where i = 0 to 7) can be set with a granularity of 1 or 2 through theGPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

15.4.4.10.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME bit field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access. For more information about wait monitoring, see Section 15.4.4.9.3.1, *Wait Pin Monitoring Control*.

15.4.4.10.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory device data capture GPMC_CLK edge in synchronous write mode. For more information about wait monitoring, see Section 15.4.4.9.3.1, *Wait Pin Monitoring Control*.

15.4.4.10.10 Bus Keeping Support

At the end cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completes to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

15.4.4.11 NOR Access Description

For each chip-select configuration, the read access can be specified as asynchronous or synchronous access through the GPMC_CONFIG1_i[29] READTYPE bit (where i = 0 to 7). For each chip-select configuration, the write access can be specified as synchronous or asynchronous access through the GPMC_CONFIG1_i[27] WRITETYPE bit where (i = 0 to 7).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For more information about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

NOTE: The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

15.4.4.11.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

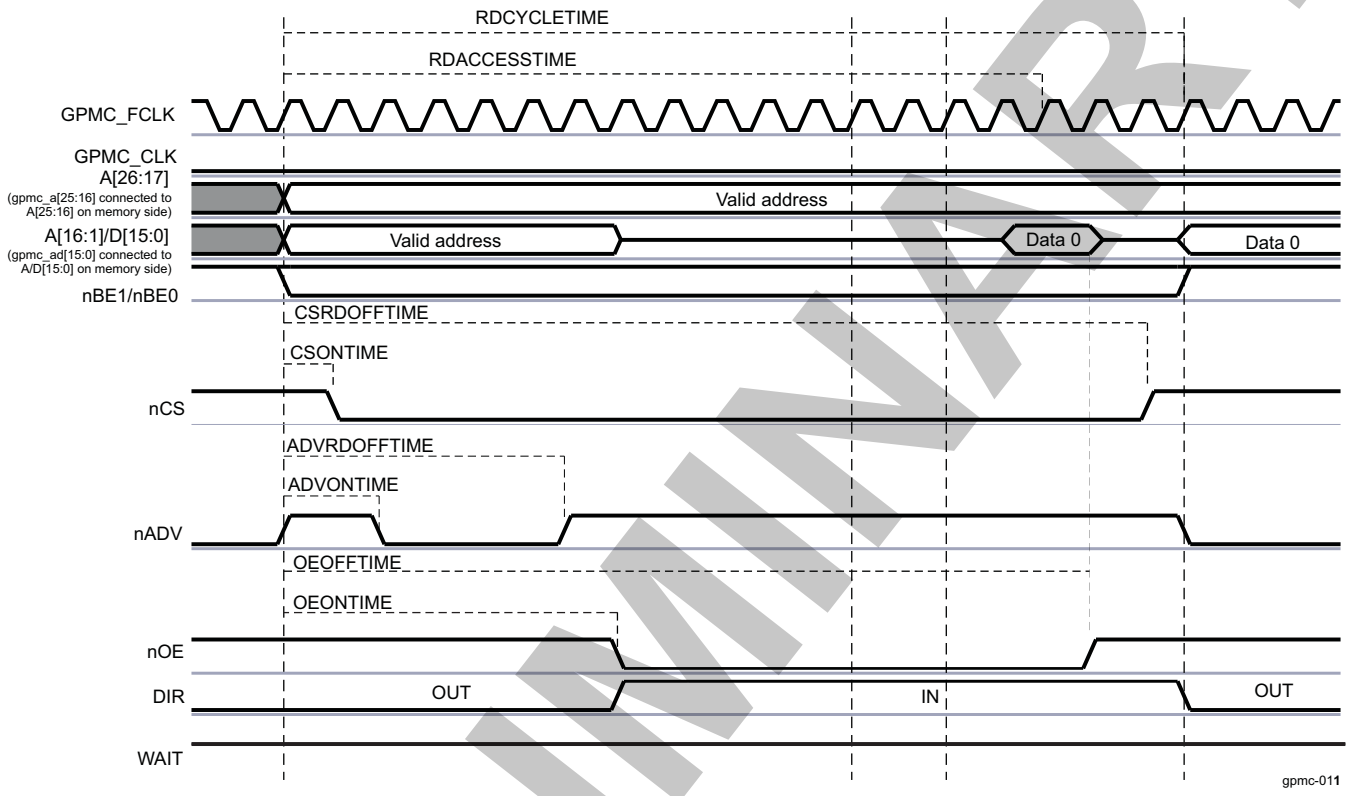
15.4.4.11.1.1 Access on Address/Data Multiplexed Devices

15.4.4.11.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 15-62 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 15-62. Asynchronous Single Read on an Address/Data-Multiplexed Device



For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-374 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits gpmc_a[25:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

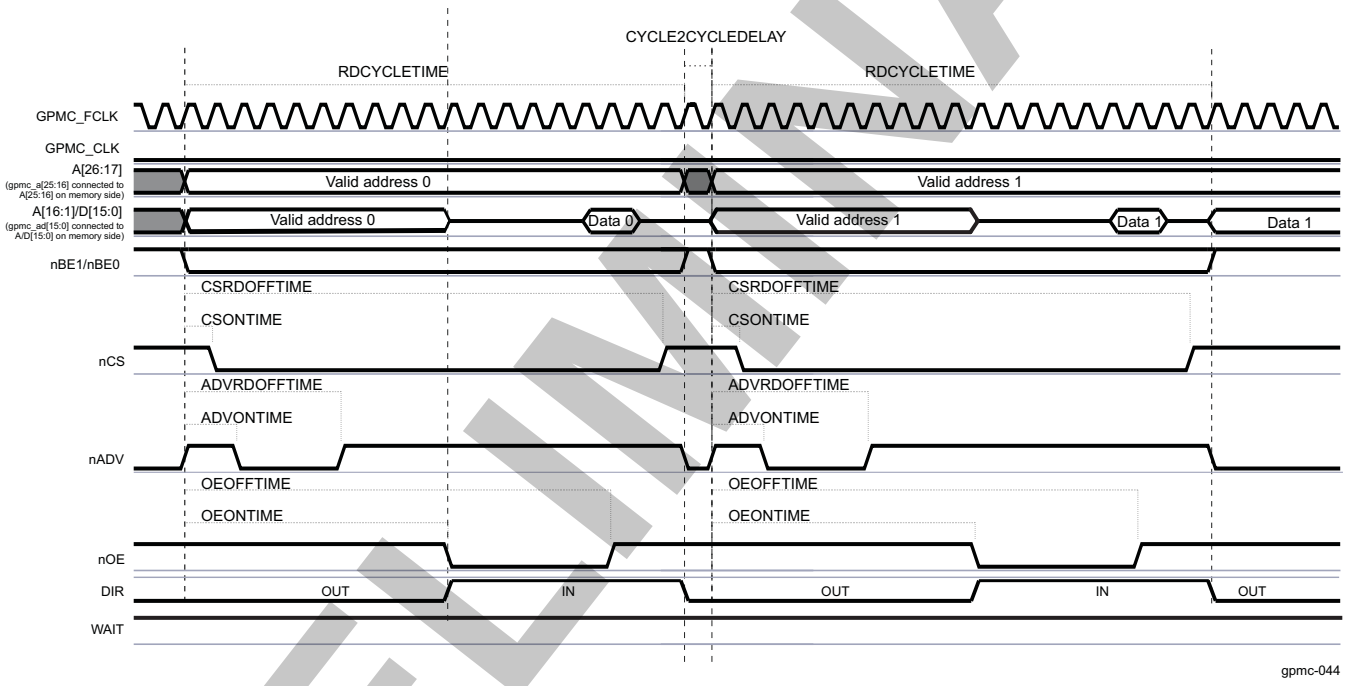
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the GPMC_CONFIG5_i[4:0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see Section 15.4.4.11.5, *System Burst Versus External Device Burst Support*.

Between two successive accesses, if an nCS pulse is needed:

- The GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY bit field can be programmed with the GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

Figure 15-63. Two Asynchronous Single-Read Accesses on an Address/Data-Multiplexed Device (32-Bit Read Split Into 2 x 16-Bit Read)



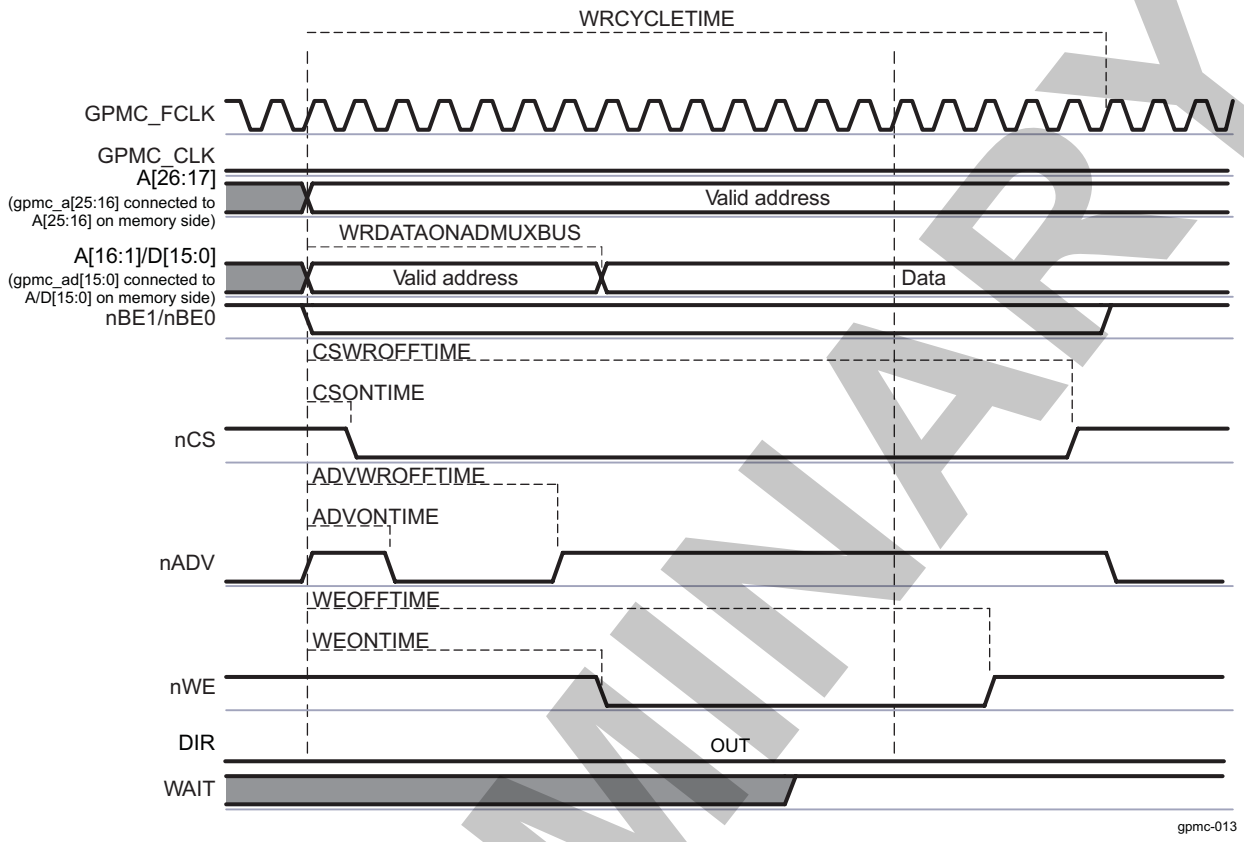
15.4.4.11.1.2 Asynchronous Single-Write Operation on an Address/Data-Multiplexed Device

Figure 15-64 shows an asynchronous single-write operation on an address/data-multiplexed device.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 15-64. Asynchronous Single-Write on an Address/Data-Multiplexed Device



For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-374 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

The nCS and nADV signals are controlled in the same way as for a asynchronous single-read operation on an address/data-multiplexed device.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19:16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28:24] WEOFFTIME bit field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC_CONFIG5_i[12:8] WRCYCLETIME parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS time.

NOTE: Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 15.4.4.10.10, *Bus Keeping Support*.

15.4.4.11.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on nonmultiplexed devices, see Section 15.4.4.11.3, *Asynchronous and Synchronous Accesses in Nonmultiplexed Mode*.

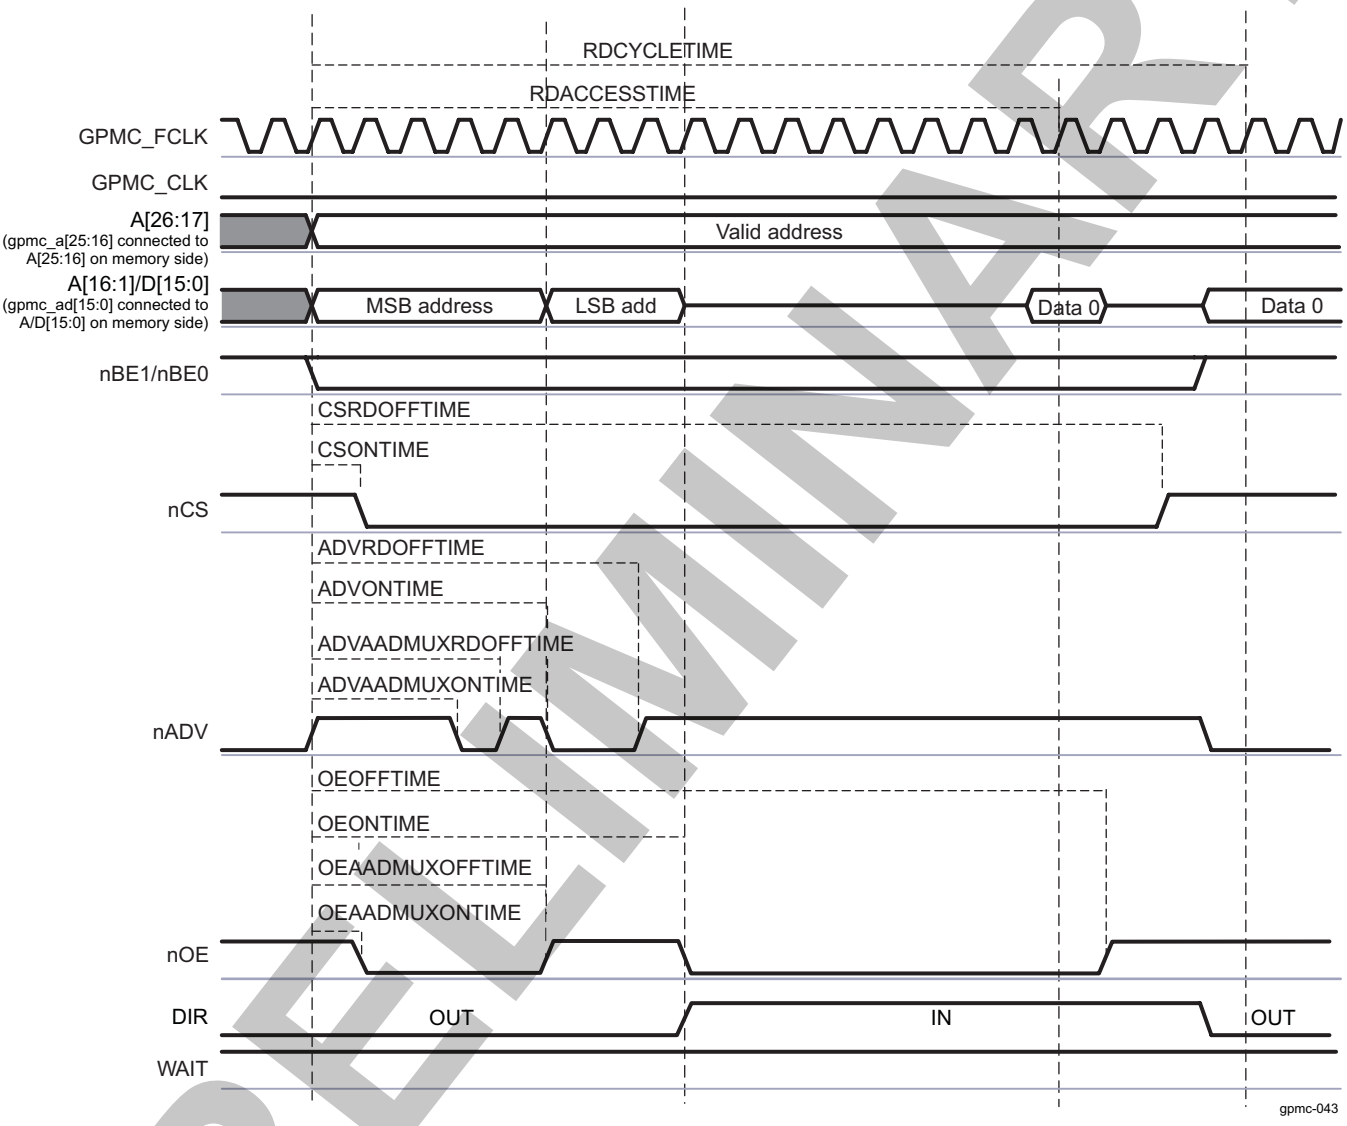
15.4.4.11.1.2 Access on Address/Address/Data-Multiplexed Devices

15.4.4.11.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 15-65 shows an asynchronous single-read operation on an AAD-multiplexed device.

Figure 15-65. Asynchronous Single Read on an AAD-Multiplexed Device



For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-374 lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS and DIR signals are controlled in the same way as for an asynchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
- nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
- nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.

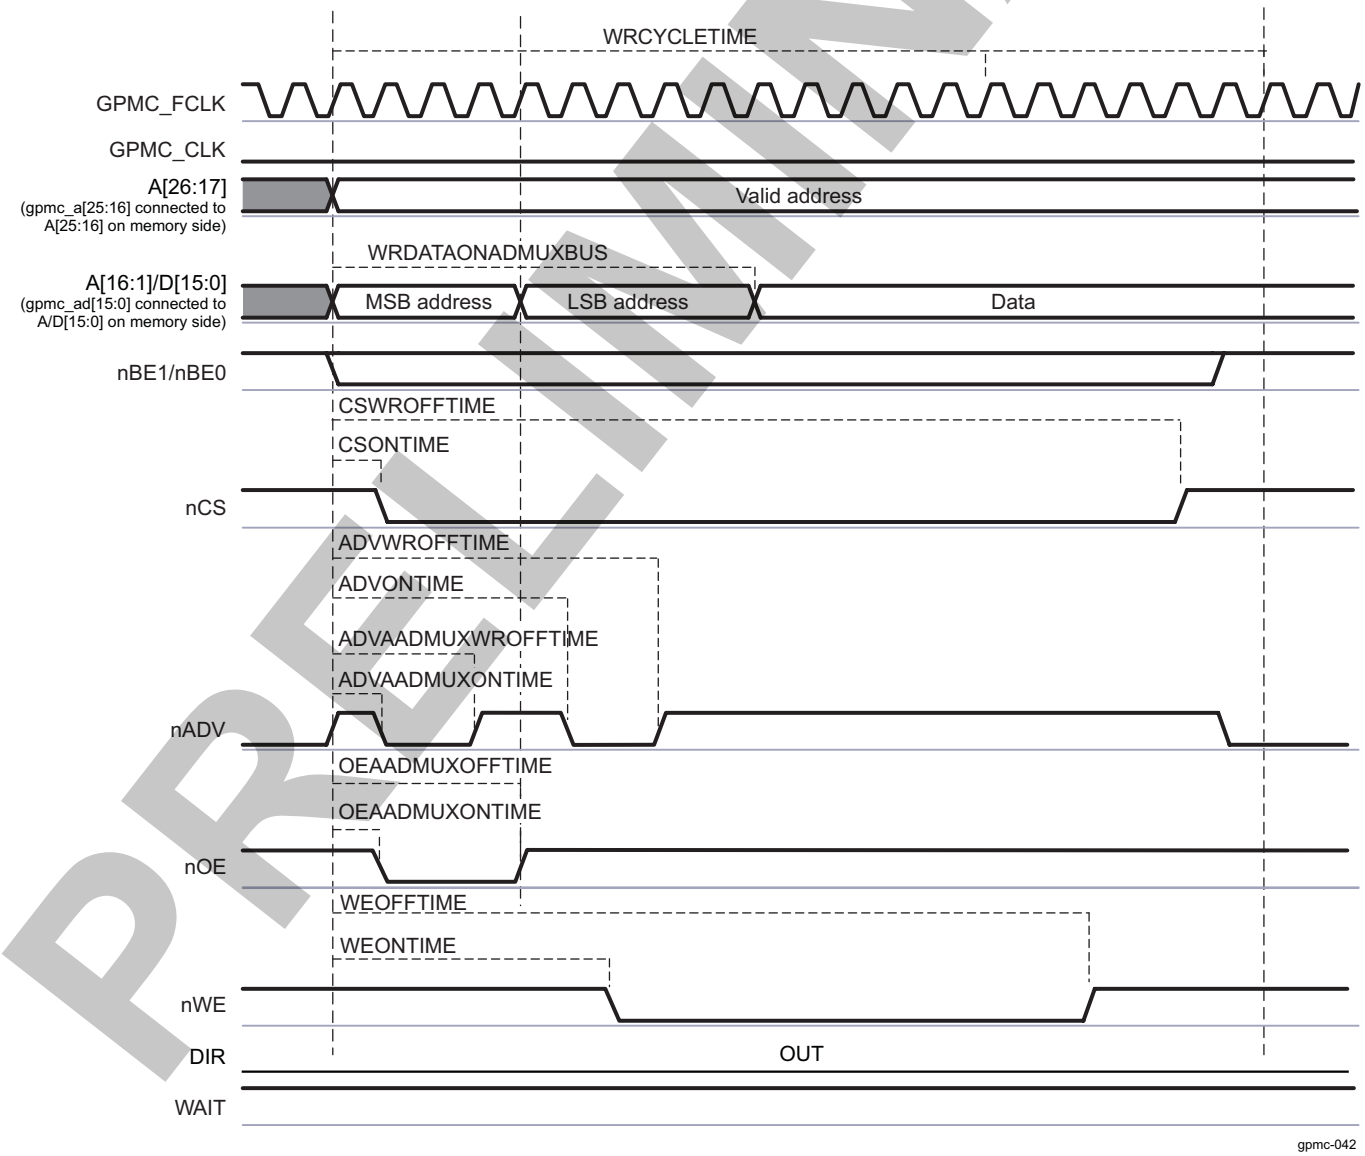
• Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):

- nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
- nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.
- nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
- nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

15.4.4.11.1.2.2 Asynchronous Single-Write Operation on an AAD-Multiplexed Device

Figure 15-66 shows an asynchronous single-write operation on an AAD-multiplexed device.

Figure 15-66. Asynchronous Single Write on an AAD-Multiplexed Device



PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-374 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for an asynchronous single-write operation on an address/data-multiplexed device. See Table 15-365.

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[30:28] ADVAADMUXWROFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[20:16] ADVWROFFTIME bit field.
- Output enable signal nOE is asserted during the address phase of a write transaction:
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS parameter.

15.4.4.11.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on nonmultiplexed devices, see Section 15.4.4.11.3, *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

15.4.4.11.2 Synchronous Access Description

This section describes read and write synchronous accesses on address/data-multiplexed devices. All information in this section can be applied to any type of memory (nonmultiplexed, address and data-multiplexed, or AAD-multiplexed) with the difference limited to the address phase. For accesses on nonmultiplexed devices, see Section 15.4.4.11.3, *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field. In the following section i stands for the chip-select number, i = 0 to 7.
- The GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field specifies that the GPMC_CLK is provided outside the GPMC for 0 to 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completes.

15.4.4.11.2.1 Synchronous Single Read

Figure 15-67 and Figure 15-68 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

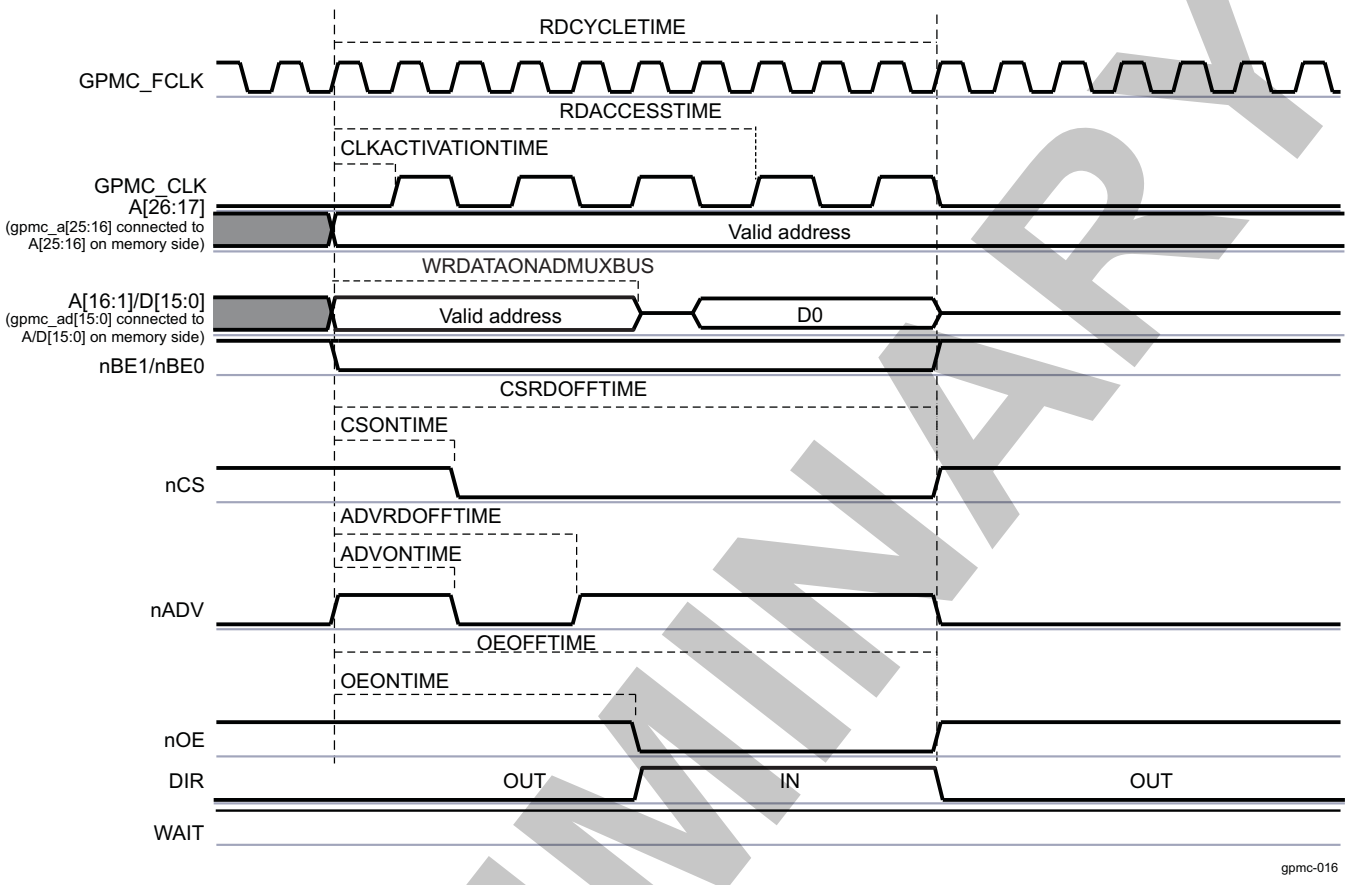
Figure 15-68. Synchronous Single Read (GPMCFCLKDIVIDER = 1)



For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-374 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field or by monitoring the WAIT signal.
- Total access time (the GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS and DIR signals are controlled in the same way as for a synchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 15.4.4.10.10, *Bus Keeping Support*.

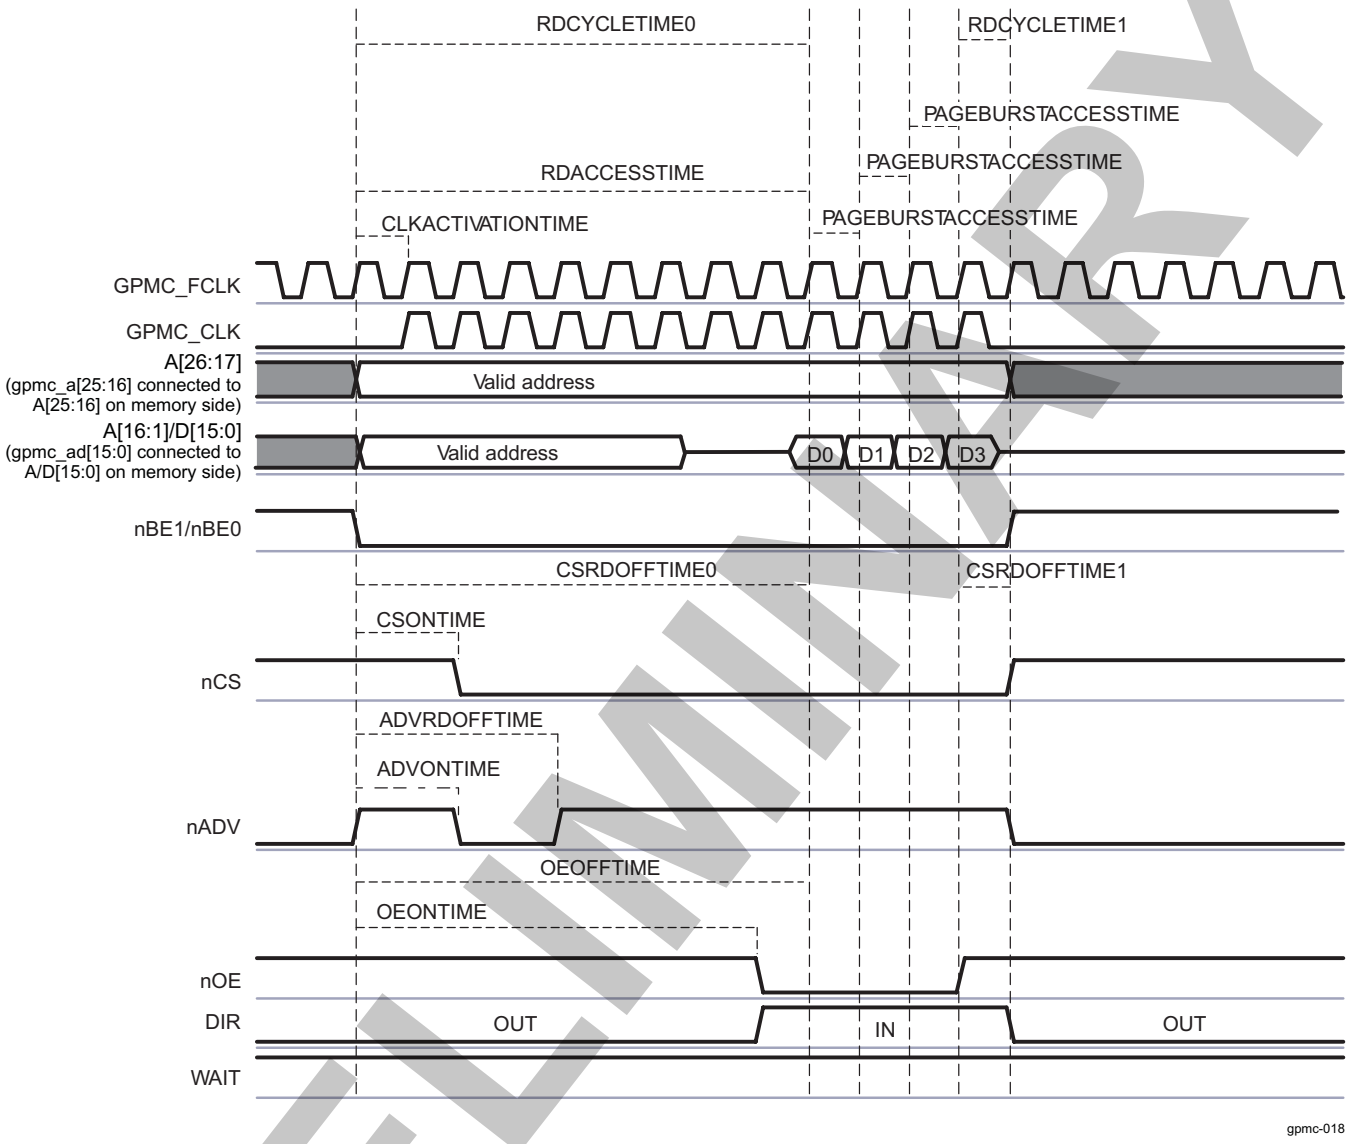
15.4.4.11.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

Figure 15-69 and Figure 15-70 show a synchronous multiple-read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

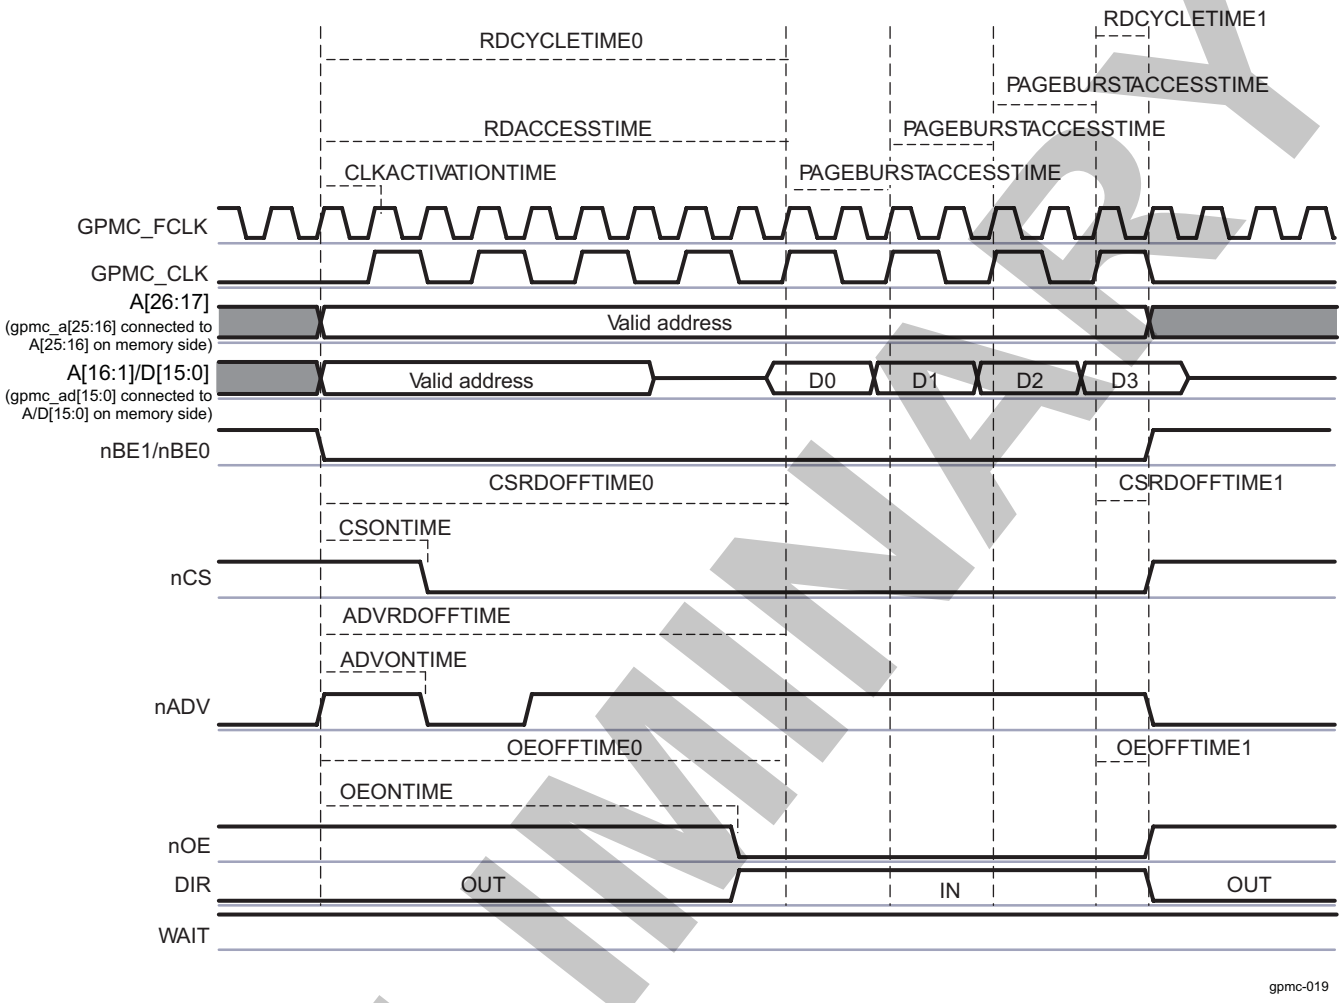
Figure 15-69. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)



PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 15-70. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)



When the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as for a synchronous single-read operation. See Table 15-360.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device every one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field and the memory-device internal configuration. Depending on the device page length, the GPMC checks the device page crossing during a new burst request and purposely inserts initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i[4:0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In Figure 15-70, the programmed value of RDCYCLETIME equals RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 15.4.4.10.10, *Bus Keeping Support*.

Burst wraparound is enabled through the GPMC_CONFIG1_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field.

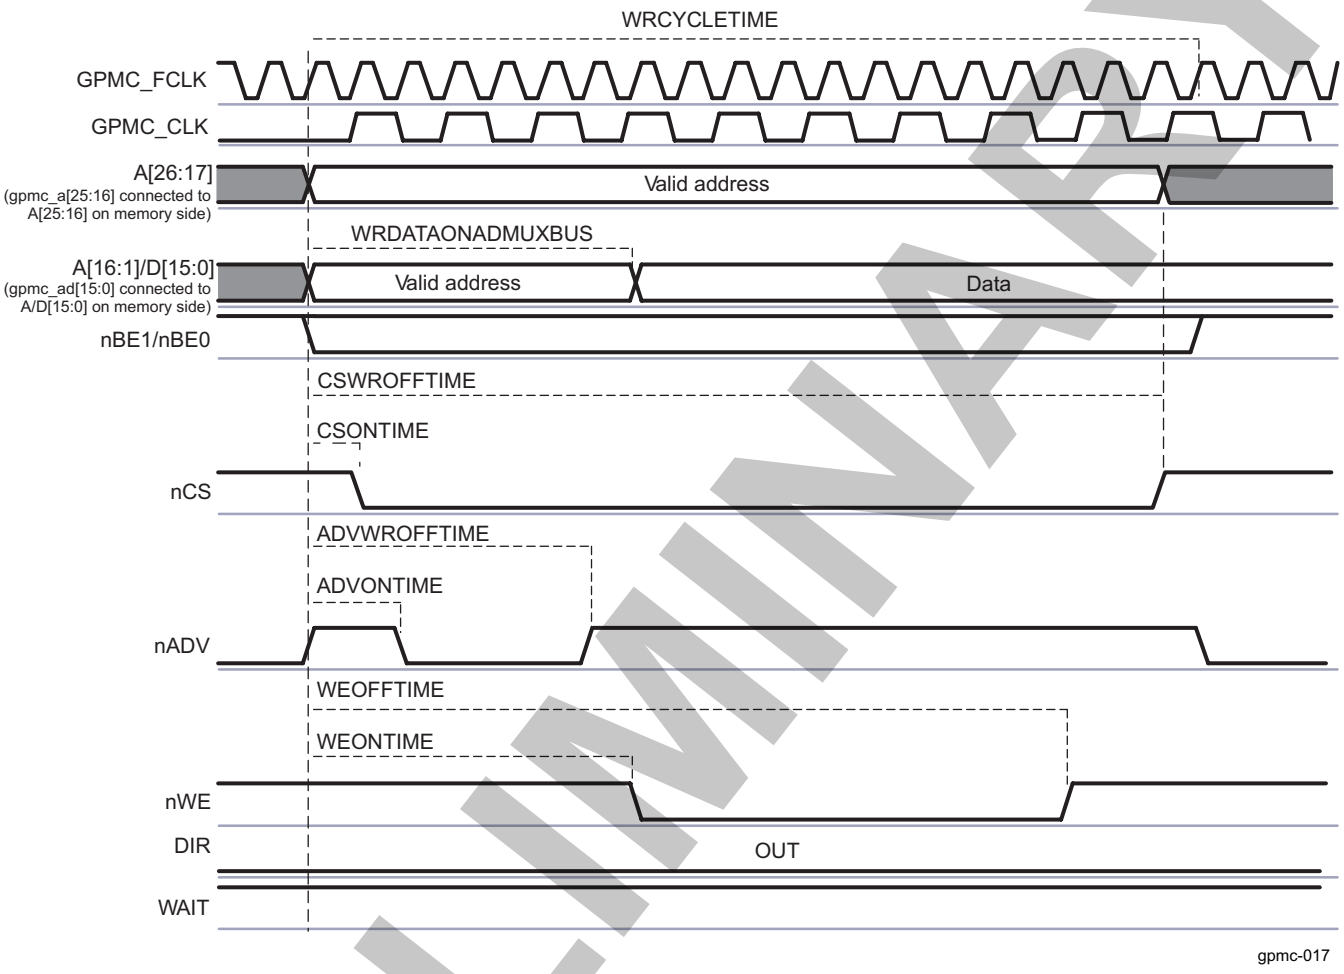
15.4.4.11.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

Figure 15-71. Synchronous Single Write on an Address/Data-Multiplexed Device



When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS bit field time. The first data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

15.4.4.11.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 15-72 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 15-72. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

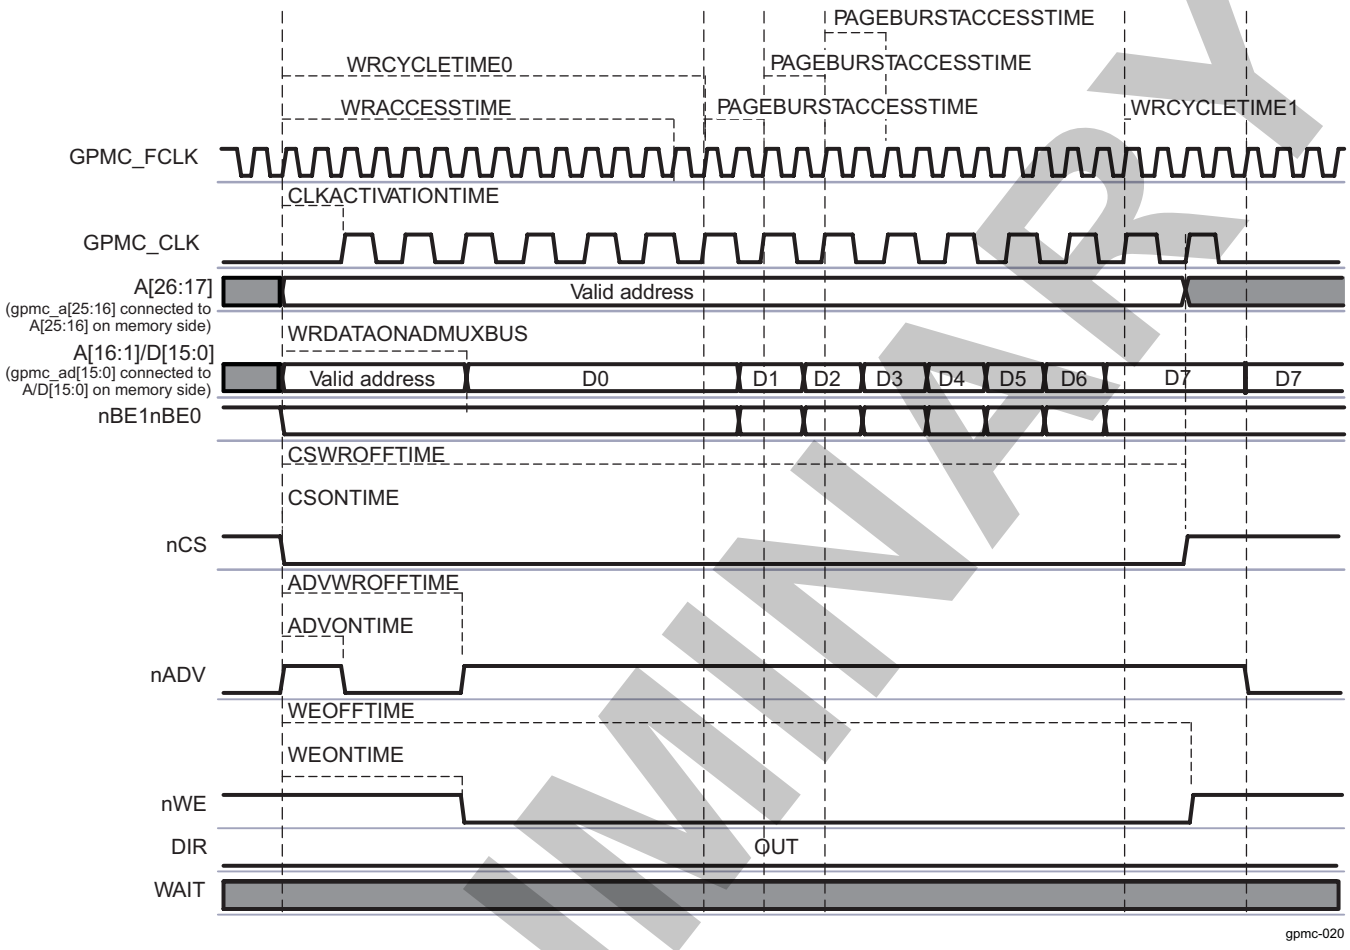


Figure 15-73 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

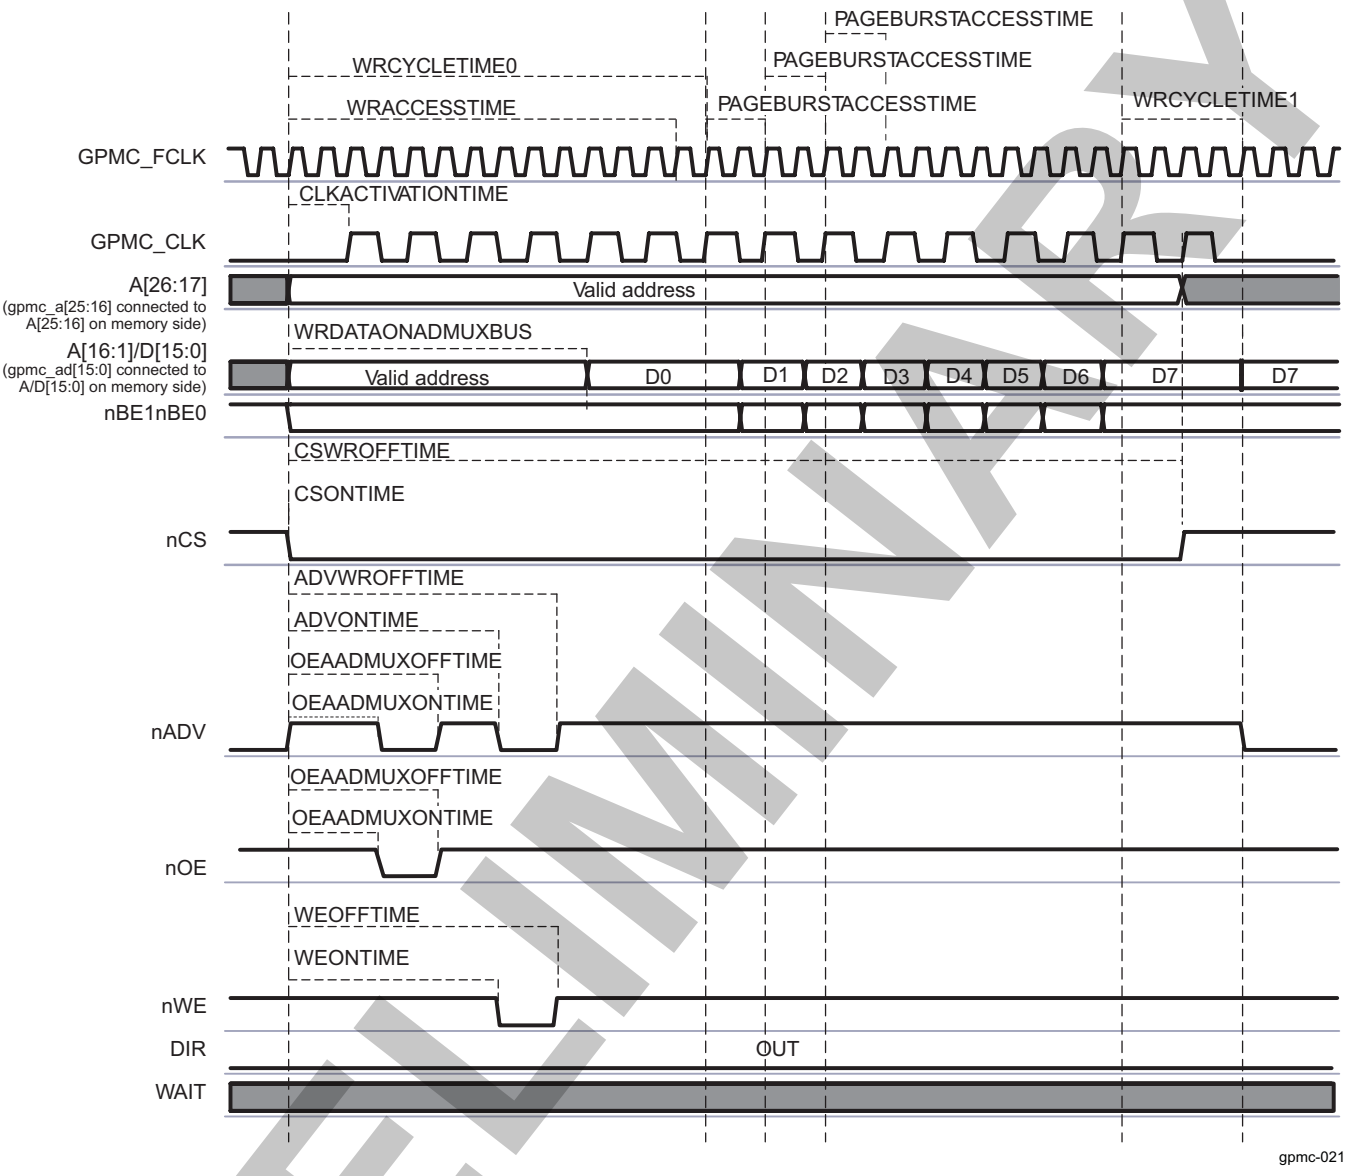
PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 15-73. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode



The first data of the burst is driven on the A/D bus at the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS bit field.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field (where i = 0 to 7) and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC_CONFIG2_i[20:16] CSWROFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[20:16] ADVWROFFTIME bit field.
- Write enable signal nWE:
  - nWE assertion indicates a read cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19:16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28:24] WEOFFTIME bit field.

NOTE: The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus, because some new devices require the nWE signal to be low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as previously described..

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG4_i[15:13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

First write data is driven by the GPMC at GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS, when in address/data-multiplexed configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i[12:8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i[28:24] bit field.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i[12:8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In Figure 15-72, the programmed value of WRCYCLETIME equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 15.4.4.10.10, *Bus Keeping Support*.

15.4.4.11.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is available only in nonmultiplexed mode. Nonmultiplexed mode is described in this section even though its use is limited (address space limited to 2KiB).

- Asynchronous single-read operation on a nonmultiplexed device
- Asynchronous single-write operation on a nonmultiplexed device

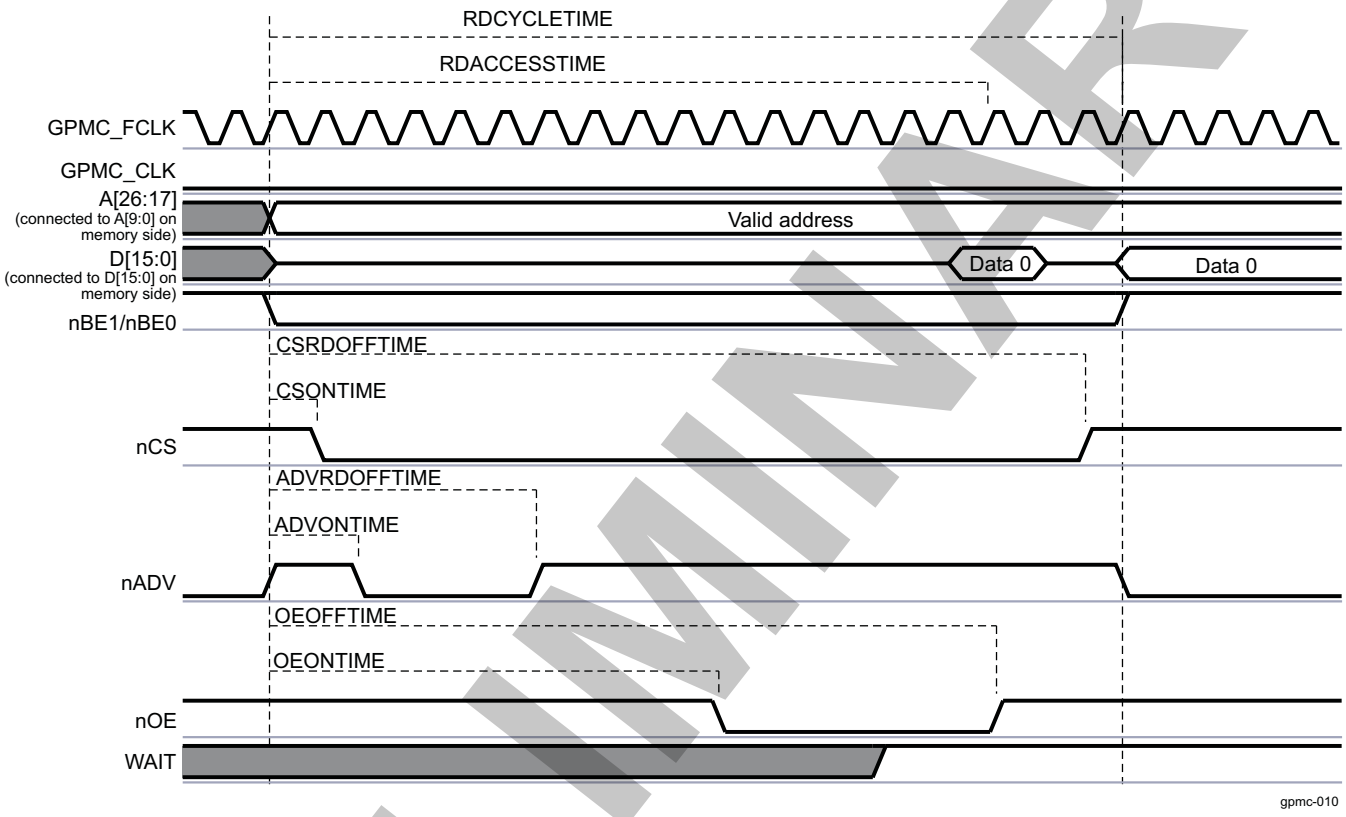
PRELIMINARY

- Asynchronous multiple- (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

15.4.4.11.3.1 Asynchronous Single-Read Operation on Nonmultiplexed Device

Figure 15-74 shows an asynchronous single-read operation on a nonmultiplexed device.

Figure 15-74. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device



The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

Read data is latched at GPMC_CONFIG1_5[20:16] RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG1_5[4:0] RDCYCLETIME parameter.

Set GPMC_CONFIG[1] LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 15-365).

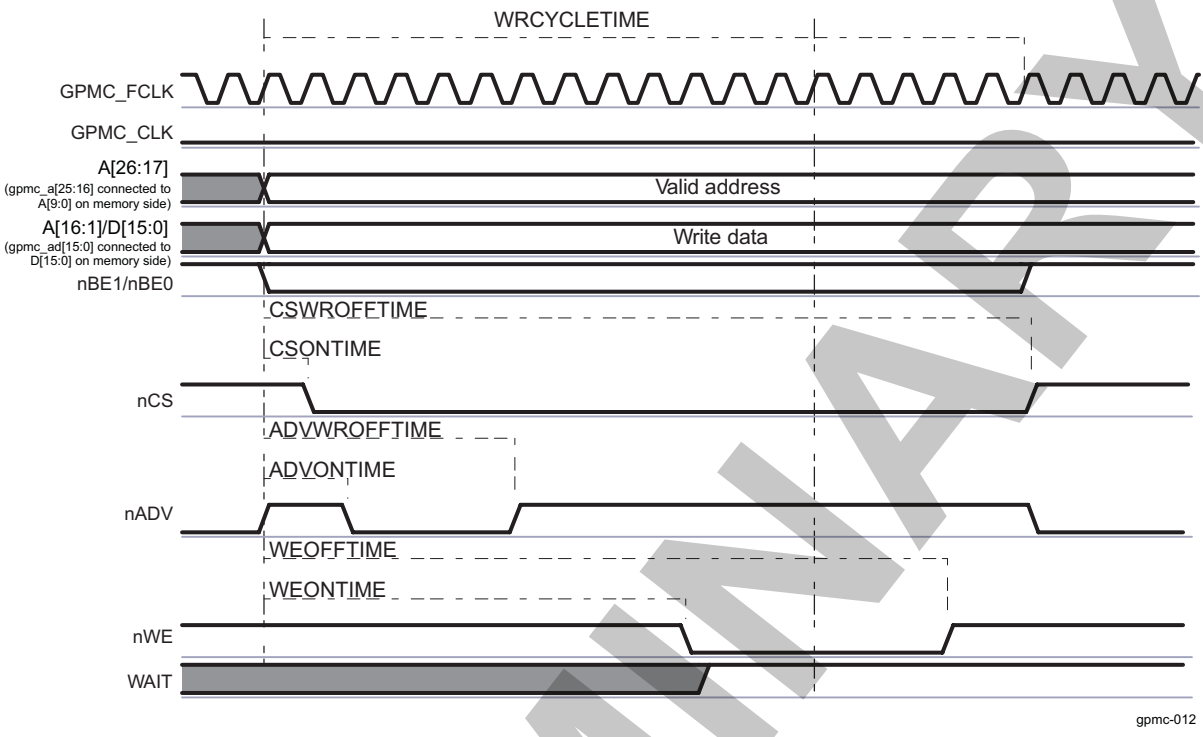
15.4.4.11.3.2 Asynchronous Single-Write Operation on Nonmultiplexed Device

Figure 15-75 shows an asynchronous single-write operation on a nonmultiplexed device.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 15-75. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device



The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

Set GPMC_CONFIG[1] LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

The nCS, nADV, nWE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 15-365).

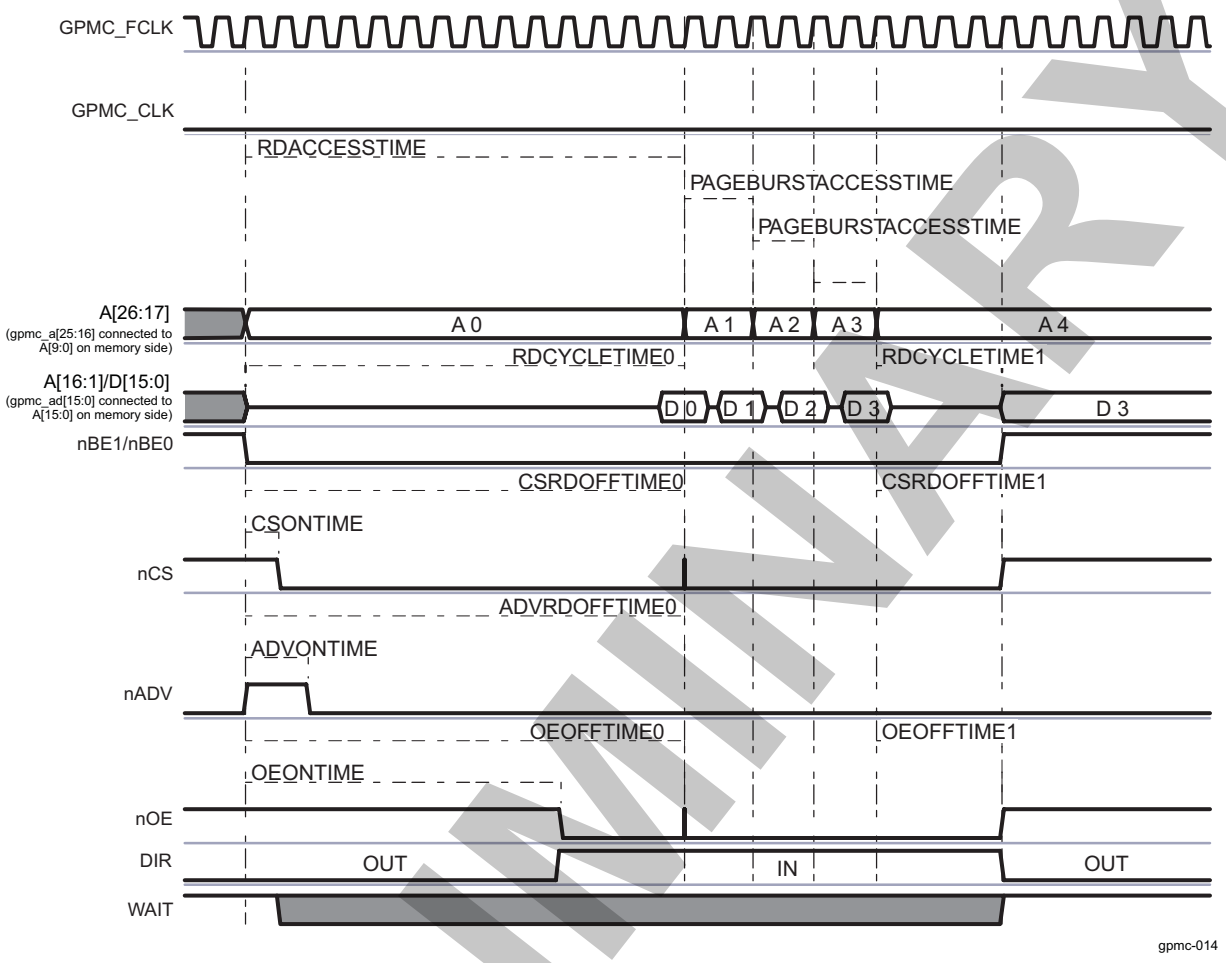
15.4.4.11.3.3 Asynchronous Multiple (Page Mode) Read Operation on Nonmultiplexed Device

Figure 15-76 shows an asynchronous multiple-read operation on a nonmultiplexed device in which two word32 host read accesses to the GPMC are split into one multiple- (page mode of 4 word16) read access to the attached device.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 15-76. Asynchronous Multiple (Page Mode) Read



NOTE: The WAIT signal is active low.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 15-365).

When RDACCESSTIME completes, control signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i[20:16] RDACCESSTIME completion time (where i = 0 to 7). The end of the access is defined by the GPMC_CONFIG5_i[4:0] RDCYCLETIME parameter.

Set GPMC_CONFIG[1] LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Page crossing is possible only with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME, plus the address hold time, starting from the nCS deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field.
- In Figure 15-76, the programmed value of RDCYCLETIME equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

PRELIMINARY

15.4.4.11.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data-multiplexed or AAD-multiplexed accesses. The only difference resides in the address phase. See Section 15.4.5.3, *GPMC Configuration in NOR Mode*.

15.4.4.11.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITMULTIPLE bits (where i = 0 to 7) are associated with the READTYPE and WRITETYPE parameters.

NOTE:

- Asynchronous write page mode is not supported.
- 8-bit-wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing

15.4.4.11.5 System Burst vs External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte-enable-controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two, four, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length bursts. The maximum length that can be issued is defined per chip-select by the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field (where i = 0 to 7). When the value of ATTACHEDDEVICEPAGELENGTH is less than the length of the system burst request (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the value of the ATTACHEDDEVICEPAGELENGTH bit field must correspond to the maximum length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit (where i = 0 to 7) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting 4 and 8 Word16-length-wrapping burst, respectively.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the value of ATTACHEDDEVICEPAGELENGTH.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed-burst length mode and a continuous-burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-word boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the value of ATTACHEDDEVICEPAGELENGTH. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait-states between data accesses. If the memory does not behave this way (nonzero wait-state burstable memory), wait pin monitoring must be enabled to dynamically control data access completion within the burst.

NOTE: When the system burst request length is less than the value of ATTACHEDDEVICEPAGELENGTH, the GPMC proceeds with the required accesses.

15.4.4.12 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i[11:10] DEVICETYPE bit field (where i = 0 to 7) must be set to 0b00.

The pSRAM device uses the NOR protocol. It supports the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or they can automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

15.4.4.13 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be deasserted if accesses to other chip-selects are requested.

15.4.4.13.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data stream-oriented (byte or 16-bit word).

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as ALE (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as CLE (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

15.4.4.13.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register (where i = 0 to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16MiB, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in Table 15-343. Failure to comply with these settings corrupts the NAND interface protocol.

Table 15-343. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] (1)	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26:25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17:16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13:12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9:8]	0b00	Nonmultiplexed mode

(1) i = 0 to 7

PRELIMINARY

Table 15-343. Chip-Select Configuration for NAND Interfacing (continued)

Bit Field	Register	Value	Comments
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1:0]	Don't care	Asynchronous mode

The GPMC_CONFIG1_i to GPMC_CONFIG4_i registers (where i = 0 to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

15.4.4.13.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver must issue the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations (where i = 0 to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations must be posted for faster operations (where i = 0 to 7). The GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers (where i = 0 to 7) are 32-bit word locations, which means any 32-or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit-wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32- or 16-bit word access to these registers, but it must consider the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers can be used, and any of the four byte locations of the registers is valid.

The same applies to a GPMC_NAND_COMMAND_i and a GPMC_NAND_ADDRESS_i (where i = 0 to 7) 32-bit word write access to a 16-bit-wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

15.4.4.13.1.3 Command Latch Cycle

Writing data at the GPMC_NAND_COMMAND_i location (where i = 0 to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.

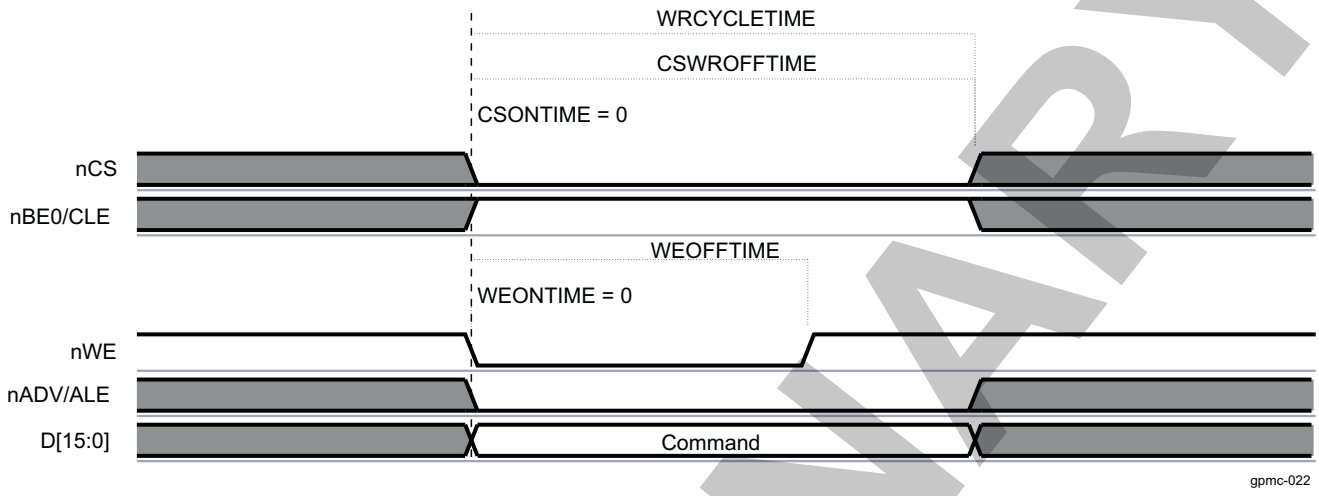
Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

- ALE and nRE (nOE) are maintained inactive.

Figure 15-77 shows the NAND command latch cycle.

Figure 15-77. NAND Command Latch Cycle



NOTE: CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND flash memories do not use byte-enable signals.

15.4.4.13.1.4 Address Latch Cycle

Writing data at the GPMC_NAND_ADDRESS_i location (where i = 0 to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 15-78 shows the NAND address latch cycle.

PRELIMINARY

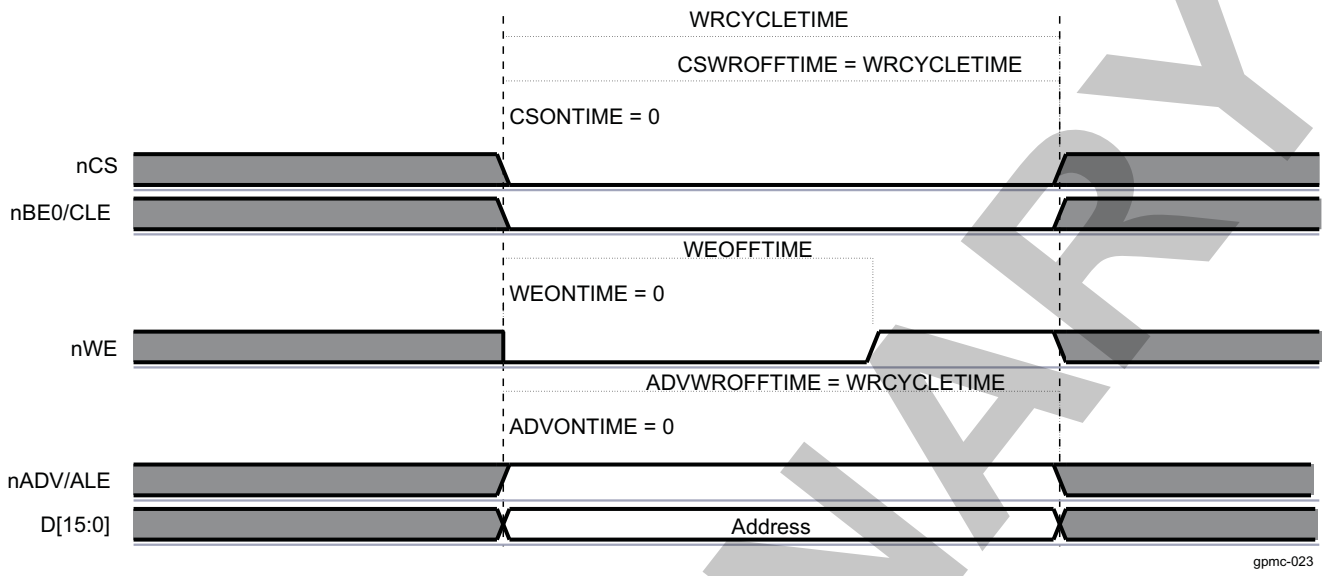
Figure 15-78. NAND Address Latch Cycle



NOTE: ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

15.4.4.13.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i location (where i = 0 to 7) mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 15-79 shows the NAND data read cycle.

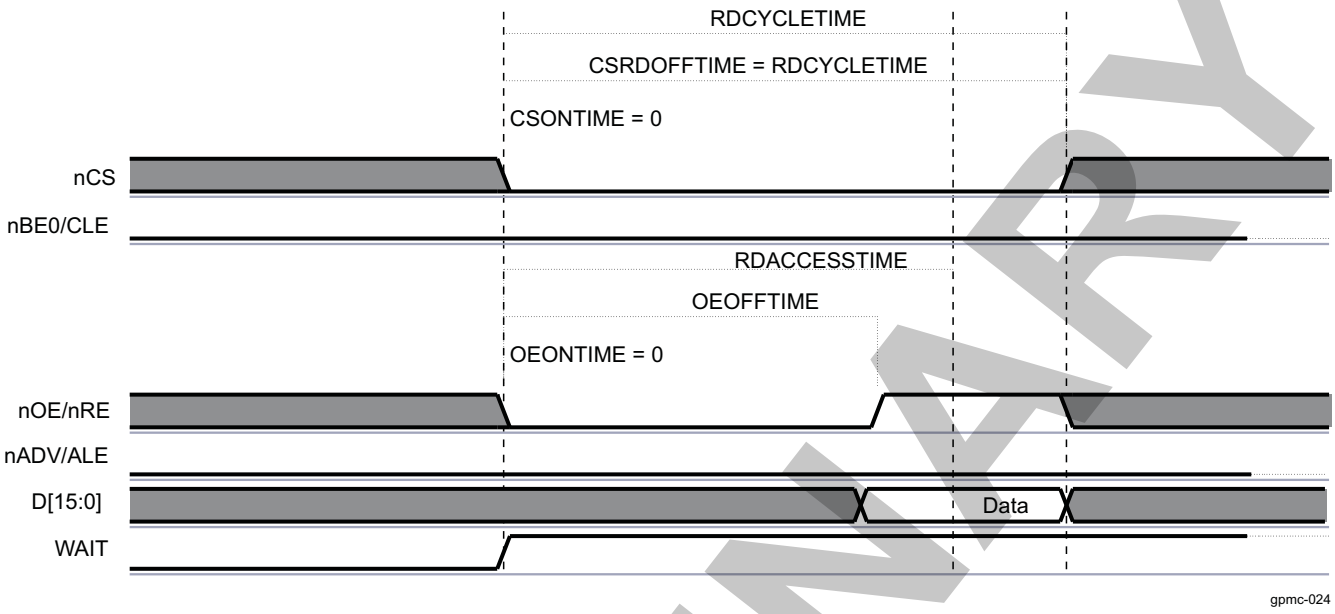
Figure 15-79. NAND Data Read Cycle

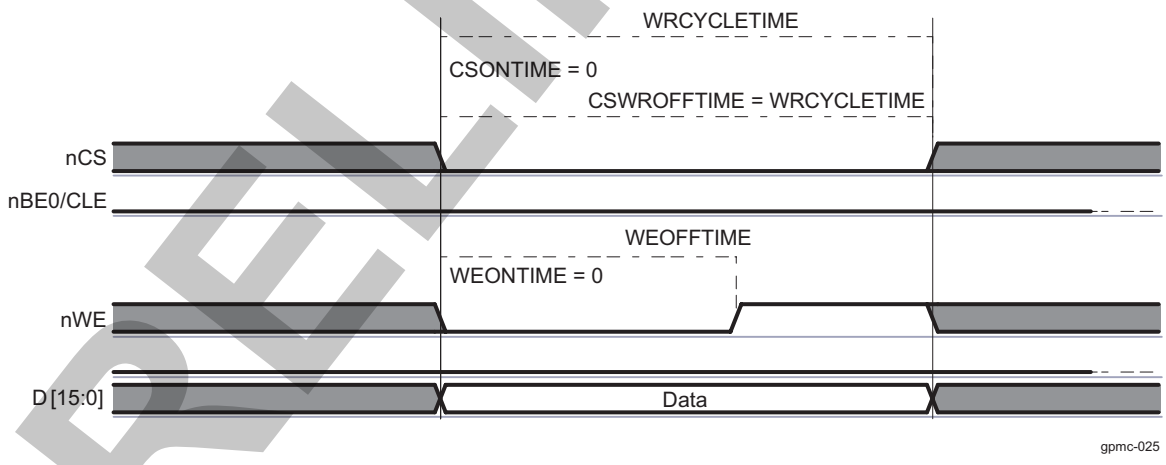


Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 15-80 shows the NAND data write cycle.

Figure 15-80. NAND Data Write Cycle



15.4.4.13.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce the following on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSRDOFFTIME
- CSWROFFTIME
- ADVRDOFFTIME
- ADVWROFFTIME
- OEOFFTIME
- WEOFFTIME

For more information about optimal prefetch engine access, see Section 15.4.4.13.4, *Prefetch and Write-Posting Engine*.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high-to-data bus in three-state mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

15.4.4.13.1.7 Read and Write Access Size Adaptation

15.4.4.13.1.7.1 8-Bit-Wide NAND Device

Host 16- and 32-bit word read and write access requests to a chip-select associated with an 8-bit-wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit-wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the cs is associated with an 8-bit-wide NAND device.

15.4.4.13.1.7.2 16-Bit-Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit-wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit-wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit-wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit-wide NAND device must be avoided, especially when ECC calculation is enabled. 8- or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit-wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

15.4.4.13.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the wait GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

NOTE: If a read access to a NAND flash is done using wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i[21] WAITWRITEMONITORING and GPMC_CONFIG1_i[22] WAITREADMONITORING bits to 0, where i = 0 to 7), and use one of the following methods instead:

- Use software to poll the WAITxSTATUS bit (where x = 0 to 2) of the GPMC_STATUS .
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed wait bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

15.4.4.13.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit (where x = 0 to 2). Software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

15.4.4.13.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits (where x = 0 to 2) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (where x = 0 to 2) of the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME bit field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the gpmc_wait pin used for NAND device ready signal monitoring.

15.4.4.13.3 ECC Calculator

The GPMC includes an error code correction (ECC) calculator circuitry that enables ECC calculation on the fly during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND flash organized with page size greater than 512 bytes
2. Bose-Chaudhurl-Hocquenghem (BCH) code for 4- to 16-bit error correction

The GPMC does not handle the error code correction directly. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (2D) (row and column) bit parity accumulation. This parity accumulation is accomplished on the programmed number of bytes or 16-bit words read from the memory device, or is written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG[3:1] ECCCS bit field. Even if two chip-selects use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

15.4.4.13.3.1 Hamming Code

All references to ECC in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a 2D (row and column) bit parity accumulation known as the Hamming code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and the software NAND driver must read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time, and parallel computations on different chip-selects are not possible. Because it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. Software must ensure that only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is complete.

15.4.4.13.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, where j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially: one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC_ECCj_RESULT register is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The GPMC_ECC_CONTROL[3:0] ECCPOINTER bit field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC_ECCj_RESULT register (where j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC_ECCj_RESULT register (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC_ECCj_RESULT register, where j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits (where j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in the GPMC_ECCj_RESULT register).

The ECCSIZE0 and ECCSIZE1 bit fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-KiB data page, 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8] RESULTSIZE bits are set to 0, and the ECC9RESULTSIZE bit is set to 1.

15.4.4.13.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG[3:1] ECCCS bit field selects the allocated chip-select. The GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The following fields must not be changed or cleared while an ECC computation is in progress:

- CCPOINTER
- ECCCLEAR
- ECCSIZE
- ECCjRESULTSIZE (where j = 1 to 9)
- ECC16B
- ECCCS

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 15-344 describes the ECC enable settings.

Table 15-344. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0–3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0–7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0–7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

Table 15-344. ECC Enable Settings (continued)

Bit Field	Register	Value	Comments
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE0
ECCjRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

15.4.4.13.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 15-81 and Figure 15-82. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

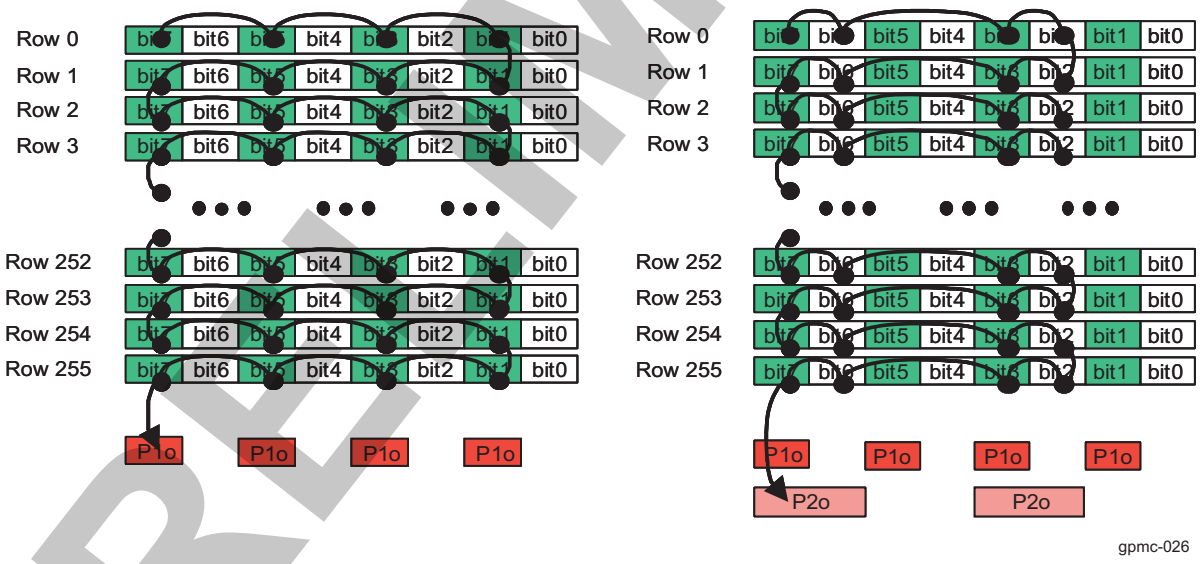
P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream
P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream
P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream
P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 15-81. Hamming Code Accumulation Algorithm (1/2)



For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254
P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253
P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

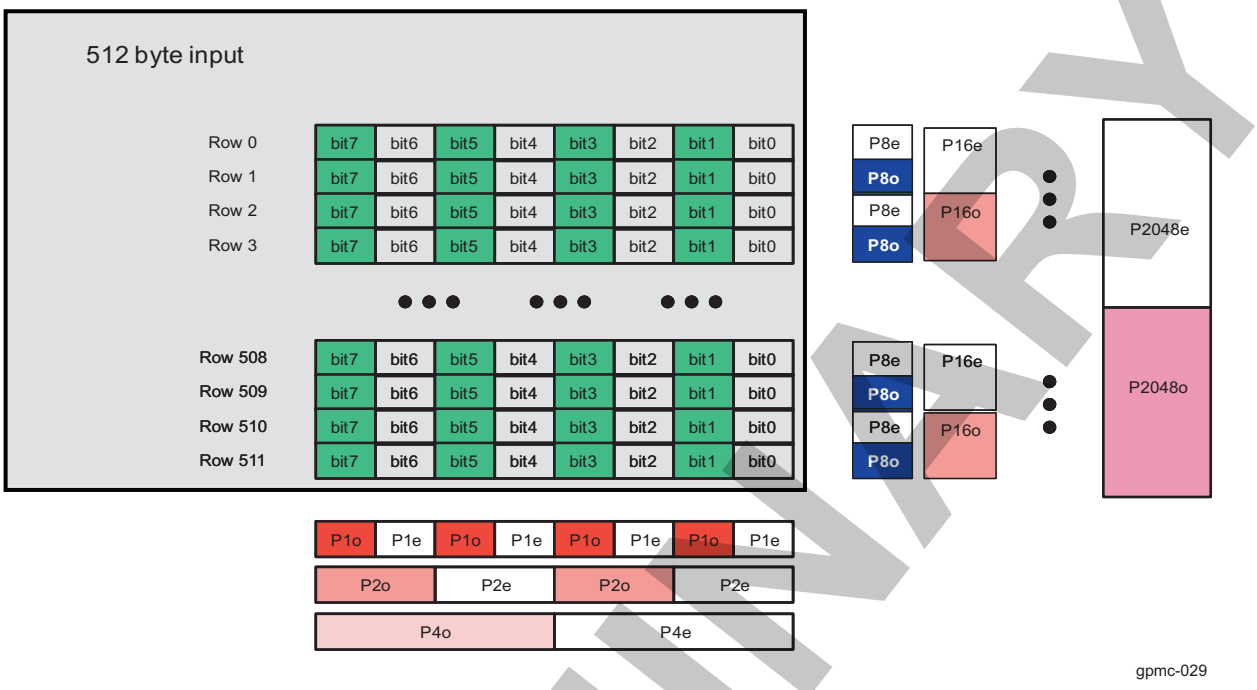
Figure 15-84. ECC Computation for a 512-Byte Data Stream (Read or Write)



For a 2-KiB page, four 512 bytes ECC calculations plus 1 for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (where j = 1 to 9).

15.4.4.13.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, 1 bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). Software must correct the corresponding bit.
- If only 1 bit in the parity result is 1, it is an ECC error and the read data is correct.

15.4.4.13.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit-based ECC computation is used for 8-bit-wide NAND device interfacing.

The 8-bit-based ECC computation can be used for 16-bit-wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit-wide NAND devices. In this case, the 16-bit-wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the LSB of the 16-bit-wide data is ordered first in the byte stream used for 8-bit-based ECC computation.

15.4.4.13.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on an 16-bit word is used for 16-bit-wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit-wide NAND device, and the GPMC_ECC_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit-wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit-based ECC and on columns for a 16-bit based ECC. Figure 15-85 and Figure 15-86 show a 128 Word16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

Figure 15-85. 128 Word16 ECC Computation

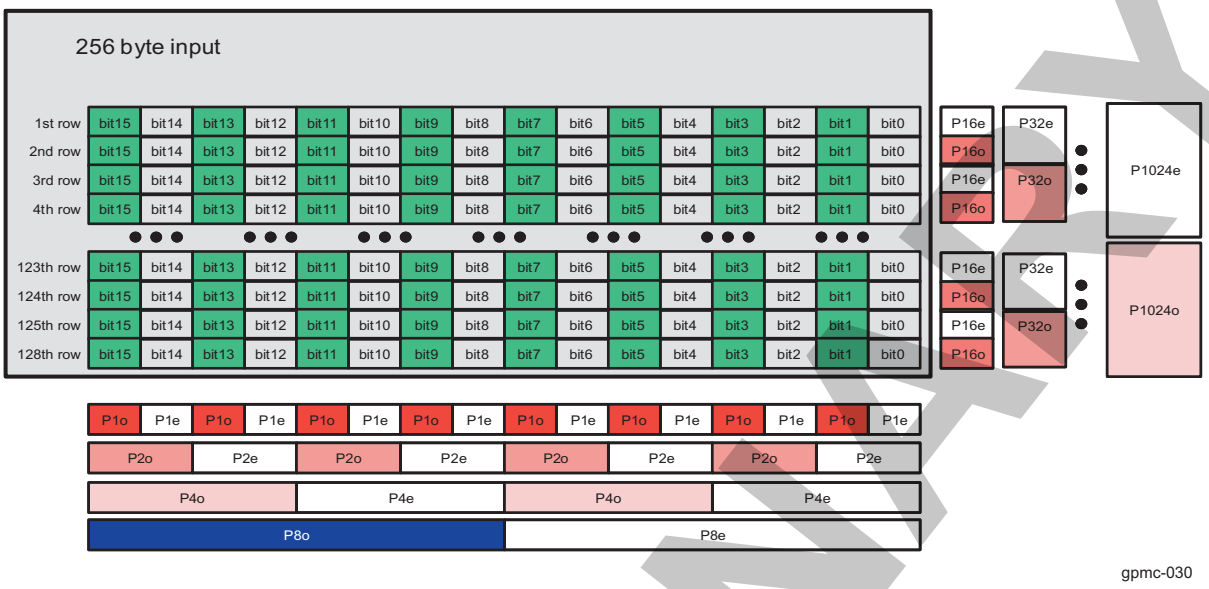

Figure 15-86. 256 Word16 ECC Computation

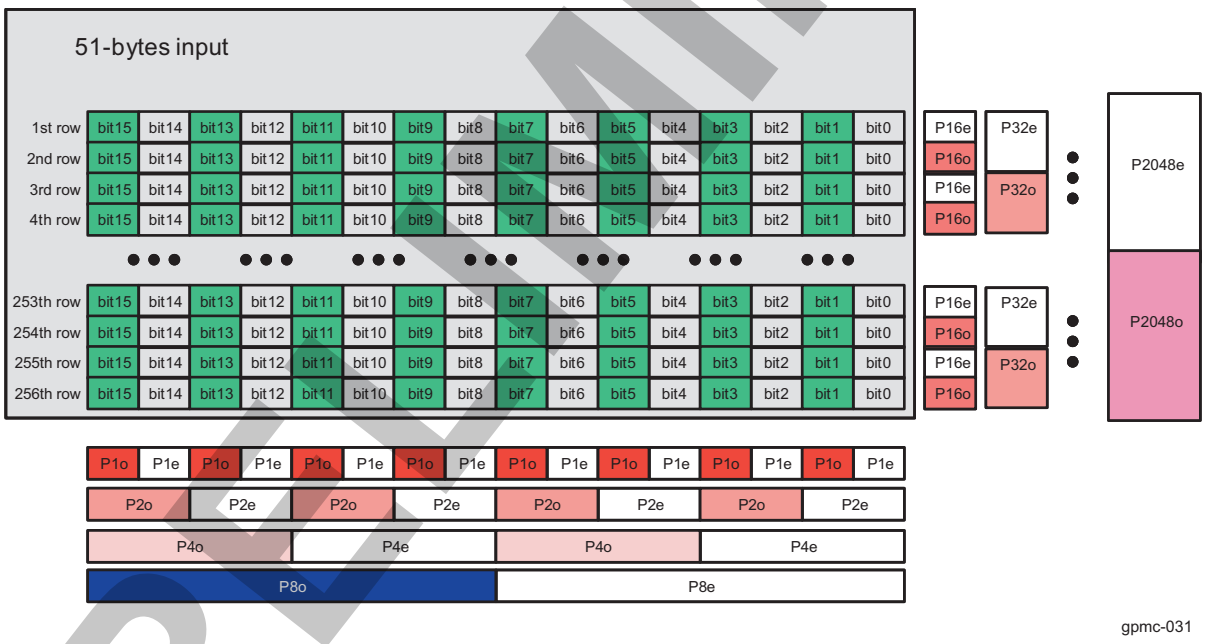

15.4.4.13.3.2 BCH Code

All references to ECC in this subsection refer to the 4- to 16-bit error correction BCH code.

15.4.4.13.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, and then some spare bytes, including the BCH ECC (and other information). The NAND device can cache a full page, including spares, for read and write accesses.
   - Typical page write sequence:
     - Sequential write to NAND cache of main data plus spare data, for a page. ECC is calculated on the fly. Calculated ECC can be inserted on the fly in the spares or replaced by dummy

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

accesses.
  - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
  - NAND writes its cache line (page) to the array.
- Typical page read sequence:
  - Sequential read of a page. ECC is calculated on the fly.
  - The status of the ECC module buffers determines the presence of errors.

2. Accesses to several memories can be interleaved by the GPMC, but only one of those memories at a time can be a NAND using the BCH engine; in other words, only one BCH calculation (for example, for a single page) can be ongoing at any time. The sequential nature of NAND accesses ensures that the data is always written or read out in the same order. BCH-relevant accesses are selected by the chip-selects of the GPMC.
3. Each page can hold up to 4KiB of data, spare bytes not included. This means up to 8 × 512-byte BCH messages. Because all the data is written or read out first, followed by the BCH ECC, the BCH engine must be able to hold eight 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

   The BCH module can store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least four cycles of the GPMC internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least four clock cycles after optimization when using the BCH calculator.
5. The spare area is assumed to be large enough to hold the BCH ECC; that is, to have a message of at least 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (the maximum codeword is 1023 bytes long, ECC included, which leaves much space to cover spare bytes).

15.4.4.13.3.2.2 Memory Mapping of BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In a standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} – 1 = 4095$, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, 104 bits are required for 8-bit error correction, and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x), as described in Table 15-345.

Table 15-345. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message M(x)			ECC R(x)		
Bit Number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) × 8) – 1 = 4119, for a total of 3 + 13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in the following registers (where i = 0 to 7):

- GPMC_BCH_RESULT0_i
- GPMC_BCH_RESULT1_i
- GPMC_BCH_RESULT2_i
- GPMC_BCH_RESULT3_i

15.4.4.13.3.2.2.1 Memory Mapping of Data Message

The data message mapping must follow the following rules:

- Bit endianness within a byte is little-endian; that is, the bytes LSB is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LSB) represents a segment of polynomial b7 * $x^{(7+i)}$ + b6 * $x^{(6+i)}$ + ... + b0 * x^{i}
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the 16-bit words in the NAND is big-endian (that is, the same message mapped in 8- and 16-bit memories has the same content at the same byte address).

NOTE: The BCH module has no visibility over actual addresses. The most important point is the sequence of data words the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

Table 15-346 and Table 15-347 describe the mapping of the same 512-byte vector (typically, a BCH message) in the NAND memory space. The byte address is only an offset modulo 512 (0x200), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are, respectively, the bits M0 and M(2^{12}–1) of the codeword mapping discussed previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAM data word boundaries.

Table 15-346. Aligned Message Byte Mapping in 8-Bit NAND

Byte Offset	8-Bit Word
0x000	(MSB) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (LSB)

Table 15-347. Aligned Message Byte Mapping in 16-Bit NAND

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
0x000	Byte 510 (0x1FE)	(MSB) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...	...	...
0x1FE	Byte 0 (0x0)	(LSB) Byte 1 (0x1)

Table 15-348 through Table 15-353 list the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on the ECC of another sector).

Many other cases exist than those given in the previous tables; for example, where the message does not start on a word boundary.

15.4.4.13.3.2.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. Software must fetch those 13 bytes (or 6 bytes) from the module interface and then store them to the spare area (page write) in the NAND or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

It is advised, however, to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error is detected. The creation of this codeword must be made as straightforward as possible.

There are cases in which the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on the fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on the fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

15.4.4.13.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described as follows. To better understand and see the real-life read and write sequences implemented with each mode, see Section 15.4.4.13.3.2.3, *Supported NAND Page Mappings and ECC Schemes*.

For each mode:

- A sequence describes the mode in pseudo language, with, for each section, the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8 through 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

15.4.4.13.3.2.2.4 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port, containing the appropriate data, must be made. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles must be skipped, a number of unused nibbles must be programmed in GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1 In the same example, 5 nibbles to process + 3 to discard = 8 nibbles = 2 × 16-bit accesses. Software must set:

- GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 = 0x5
- GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1 = 0x3

NOTE: In the following figures, size and size0 are the same parameter.

  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

15.4.4.13.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply to the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in Section 15.4.4.13.3.2.2.1, *Memory Mapping of Data Message*.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Each of the following sections gives a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In Figure 15-88 through Figure 15-90, the tables on the left summarize the mode, size0, and size1 parameters to program for, respectively, write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC (in nibbles)
- S is the number of Sectors per page (two in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. The processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1 KiB + spares; that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can happen only in the codeword that was actually written to the NAND, not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits; that codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, the programmed sizes, and the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - All sectors: (512) + P + E
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - Sector 0 codeword: (512) + P + E
  - Other sectors: (512) + E
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - All codewords (512) + E

15.4.4.13.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the ECC for its sector.

15.4.4.13.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor affect the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default, the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64-byte (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled by the MPU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or by the sDMA through DMA request synchronization, with a programmable request byte size in prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. As a consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, engine data read and write sequencing is based solely on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

NOTE: The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

15.4.4.13.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR bit field.

In prefetch and write-posting modes, the engine uses byte or 16-bit word access requests, respectively, for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT bit fields must be programmed accordingly as a number of bytes.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

When the GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the following registers (where i = 0 to 7):

- GPMC_NAND_COMMAND_i
- GPMC_NAND_ADDRESS_i
- GPMC_NAND_DATA_i

The FIFO entry on the L3 interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER bit field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots that can be written in write-posting mode. The GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field monitors the number of remaining bytes to be read or written by the engine according to the value of the TRANSFERCOUNT bit field. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit-wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0 (that is, the FIFO is empty), a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0 (that is, the FIFO is full), a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

15.4.4.13.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started so that the ECC is computed correctly on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it sets the STARTENGINE bit only when the NAND device is in a ready state (that is, data is valid for prefetching).

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active-to-inactive WAIT signal transition is detected. The transition detector must be cleared before any transition detection (see Section 15.4.4.13.2.2, *Ready Pin Monitored by Hardware Interrupt*). The GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR bit field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit before NAND address phase completion when in synchronized mode. The prefetch engine starts when an active-to-inactive WAIT signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by the GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT bit field.

Table 15-354 describes the prefetch mode configuration.

Table 15-354. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17:16]	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 15.4.4.13.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

15.4.4.13.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an sDMA channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER bit field or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is valid only when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel that owns this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

15.4.4.13.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are calculated properly on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT accesses are complete.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must be issued only when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 15-355 describes the write-posting configuration.

Table 15-355. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.

PRELIMINARY

Table 15-355. Write-Posting Mode Configuration (continued)

Bit Field	Register	Value	Comments
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 15.4.4.13.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

15.4.4.13.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO or to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field. COUNTVALUE indicates the current number of remaining data to be written based on the value of the TRANSFERCOUNT bit field. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared before asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The value of the COUNTVALUE bit field is valid only if the write-posting engine is active and started, and an interrupt is issued only when COUNTVALUE reaches 0; that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel that owns this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request completes.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or MPU fills the FIFO with no consideration for the associated byte enables. Any byte stored in the FIFO is written into the memory device.

15.4.4.13.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i location, where i = 0 to 7) are never optimized.

The GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION bit field defines the number of GPMC_FCLK cycles to be suppressed from the following timing parameters:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSOFFTIME
- ADVOFFTIME
- OEOFFTIME
- WEOFFTIME

Figure 15-91 shows that in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION bit field.

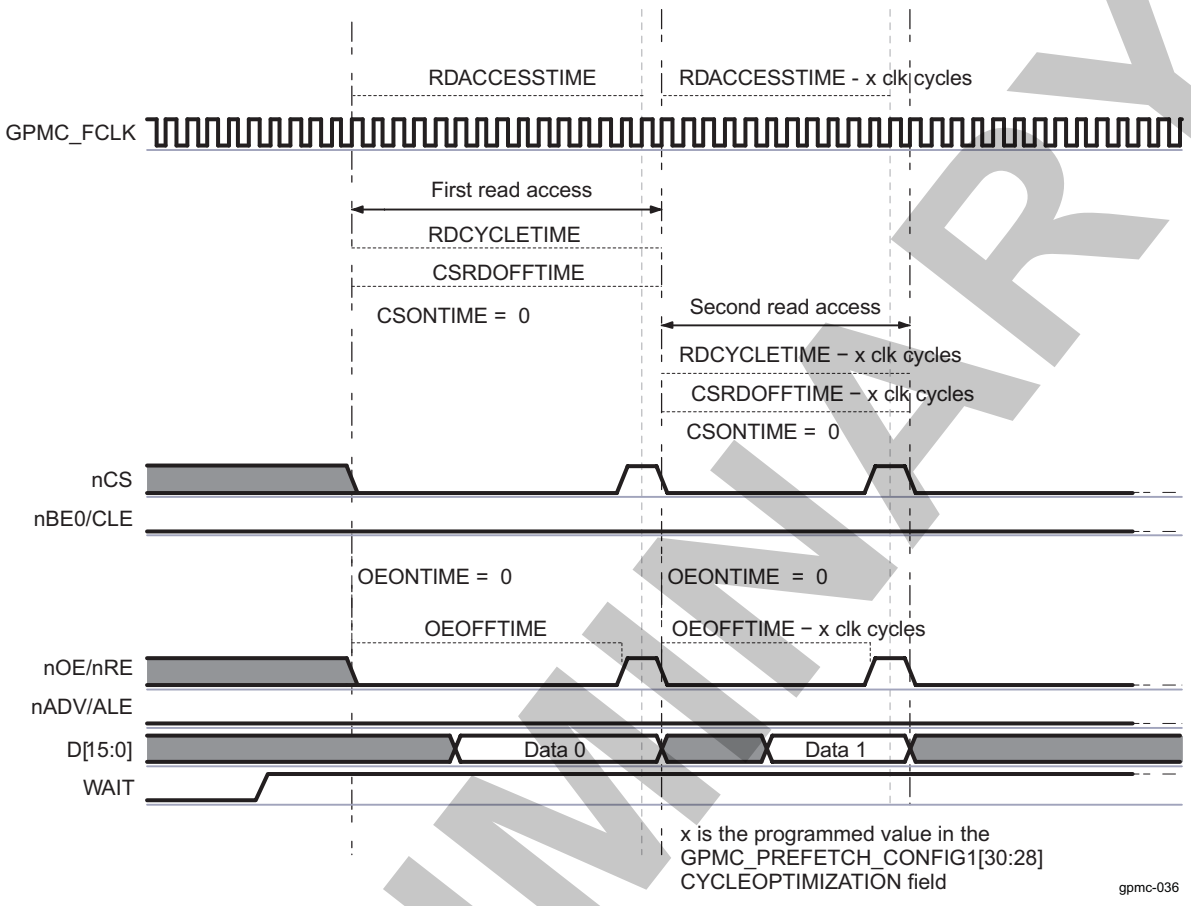
Figure 15-91. NAND Read Cycle Optimization Timing Description



15.4.4.13.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering that the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

15.4.5 GPMC Basic Programming Model

15.4.5.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top-down approach to users that need to configure the GPMC module.

Figure 15-92 and Table 15-356 through Table 15-358 show a programming model top-level diagram for the GPMC, and a description of each step. Each block of the diagram is described in one of the following sections through a set of registers to configure.

15.4.5.6.1 GPMC Timing Parameters Formulas

This section is intended to help the user calculate the GPMC timing bit field values. Formulas are not listed exhaustively.

The section describes:

- NAND flash interface timing parameters formulas
- Synchronous NOR flash timing parameters formulas
- Asynchronous NOR flash timing parameters formulas

15.4.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x2. Table 15-375 describes the NAND timing parameters.

Table 15-375. NAND Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_nwe valid time
B	ns	Delay time – gpmc_ncs valid to gpmc_nwe valid
C	ns	Delay time – gpmc_nbe0_cle/gpmc_nadv_ale high to gpmc_nwe valid
D	ns	Delay time – gpmc_ad[15:0] valid to gpmc_nwe valid
E	ns	Delay time – gpmc_nwe invalid to gpmc_ad[15:0] invalid
F	ns	Delay time – gpmc_nwe invalid to gpmc_nbe0_cle/gpmc_nadv_ale invalid
G	ns	Delay time – gpmc_nwe invalid to gpmc_ncs invalid
H	ns	Cycle time – Write cycle time
I	ns	Delay time – gpmc_ncs valid to gpmc_noe valid
J	ns	Setup time – gpmc_ad[15:0] valid to gpmc_noe invalid
K	ns	Pulse duration – gpmc_noe valid time
L	ns	Cycle time – Read cycle time
M	ns	Delay time – gpmc_noe invalid to gpmc_ncs invalid

The configuration parameters are calculated through the following formulas.

A = (WEOffTime – WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK period

B = ((WEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

C = ((WEOnTime – ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay - ADVExtraDelay)) * GPMC_FCLK period

D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEExtraDelay) * GPMC_FCLK period

E = (WrCycleTime – WEOffTime * (TimeParaGranularity + 1) – 0.5 * WEExtraDelay) * GPMC_FCLK period

F = (ADVWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay – WEExtraDelay) * GPMC_FCLK period

G = (CSWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay – WEExtraDelay) * GPMC_FCLK period

H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

I = ((OEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (OEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

J = ((AccessTime – OEOffTime) * (TimeParaGranularity + 1) – 0.5 * OEExtraDelay)) * GPMC_FCLK period

K = (OEOffTime – OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK period

L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

PRELIMINARY

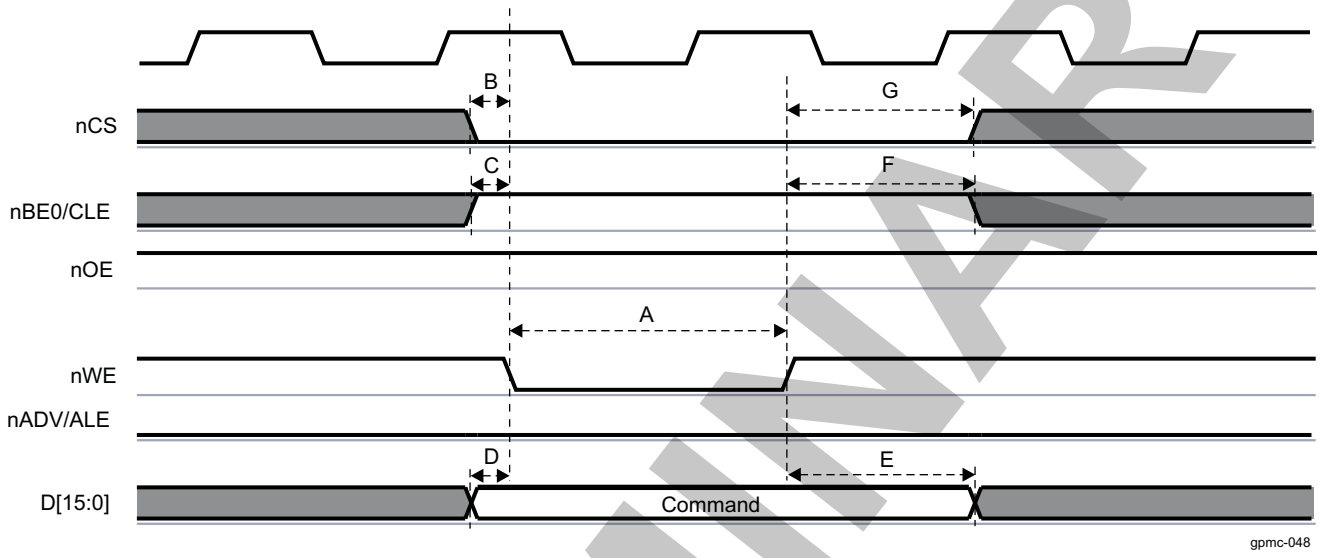
M = (CSRdOffTime – OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - OEExtraDelay) * GPMC_FCLK period

Figure 15-94 shows a simplified example of command latch cycle timing where formulas are associated with signal waves.

Figure 15-94. NAND Command Latch Cycle Timing Simplified Example



15.4.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to synchronous mode. Table 15-376 describes the synchronous NOR formulas.

Table 15-376. Synchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_ncs low
B	ns	Delay time – address bus valid to gpmc_clk first edge
		Delay time – gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_clk first edge
C	ns	Pulse duration – gpmc_nbe0_cle/gpmc_nbe1 low
D	ns	Delay time – gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 invalid
		Delay time – gpmc_clk rising edge to gpmc_nadv_ale invalid
E	ns	Delay time – gpmc_clk rising edge to gpmc_ncs invalid
		Delay time – gpmc_clk rising edge to gpmc_noe invalid
F	ns	Delay time – gpmc_clk rising edge to gpmc_ncs transition
G	ns	Delay time – gpmc_clk rising edge to gpmc_nadv_ale transition
H	ns	Delay time – gpmc_clk rising edge to gpmc_noe transition
I	ns	Delay time – gpmc_clk rising edge to gpmc_nwe transition
J	ns	Delay time – gpmc_clk rising edge to gpmc_ad data bus transition
		Delay time – gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 transition
K	ns	Pulse duration – gpmc_nadv_ale low
L	ns	Delay time – gpmc_wait invalid to first data latching gpmc_clk edge

PRELIMINARY

The configuration parameters are calculated through the following formulas.

1. For single read accesses:
   A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – ACCESSTIME) * GPMC_FCLK period
   E = (CSRDOFFTIME – ACCESSTIME) * GPMC_FCLK period
2. For burst read accesses (where n is the page burst access number):
   A = (CSRDOFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (RDCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – (ACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period
   E = (CSRDOFFTIME – (ACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period
3. For burst write accesses (where n is the page burst access number):
   A = (CSWROFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (WRCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (WRCYCLETIME – (ACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period
   E = (CSWROFFTIME – (ACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period
4. For all accesses:
   For nCS falling edge (chip-select activated):
   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 0x2:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

   For nCS rising edge (chip-select deactivated) in reading mode:
   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 0x2:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

   For nCS rising edge (chip-select deactivated) in writing mode:
   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and

CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)
F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nADV falling edge (nADV activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nADV rising edge (nADV deactivated) in reading mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nADV rising edge (nADV deactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVWROFFTIME are odd) or (CLKACTIVATIONTIME and ADVWROFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nOE falling edge (nOE activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEONTIME

PRELIMINARY

are odd) or (CLKACTIVATIONTIME and OEONTIME are even)
H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nOE rising edge (nOE deactivated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEOFFTIME are odd) or (CLKACTIVATIONTIME and OEOFFTIME are even)
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nWE falling edge (nWE activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEONTIME are odd) or (CLKACTIVATIONTIME and WEONTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nWE rising edge (nWE deactivated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEOFFTIME are odd) or (CLKACTIVATIONTIME and WEOFFTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For gpmc_nadv low pulse duration:

- Read operation:
  K = (ADVRDOFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- Write operation:
  K = (ADVWROFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

PRELIMINARY

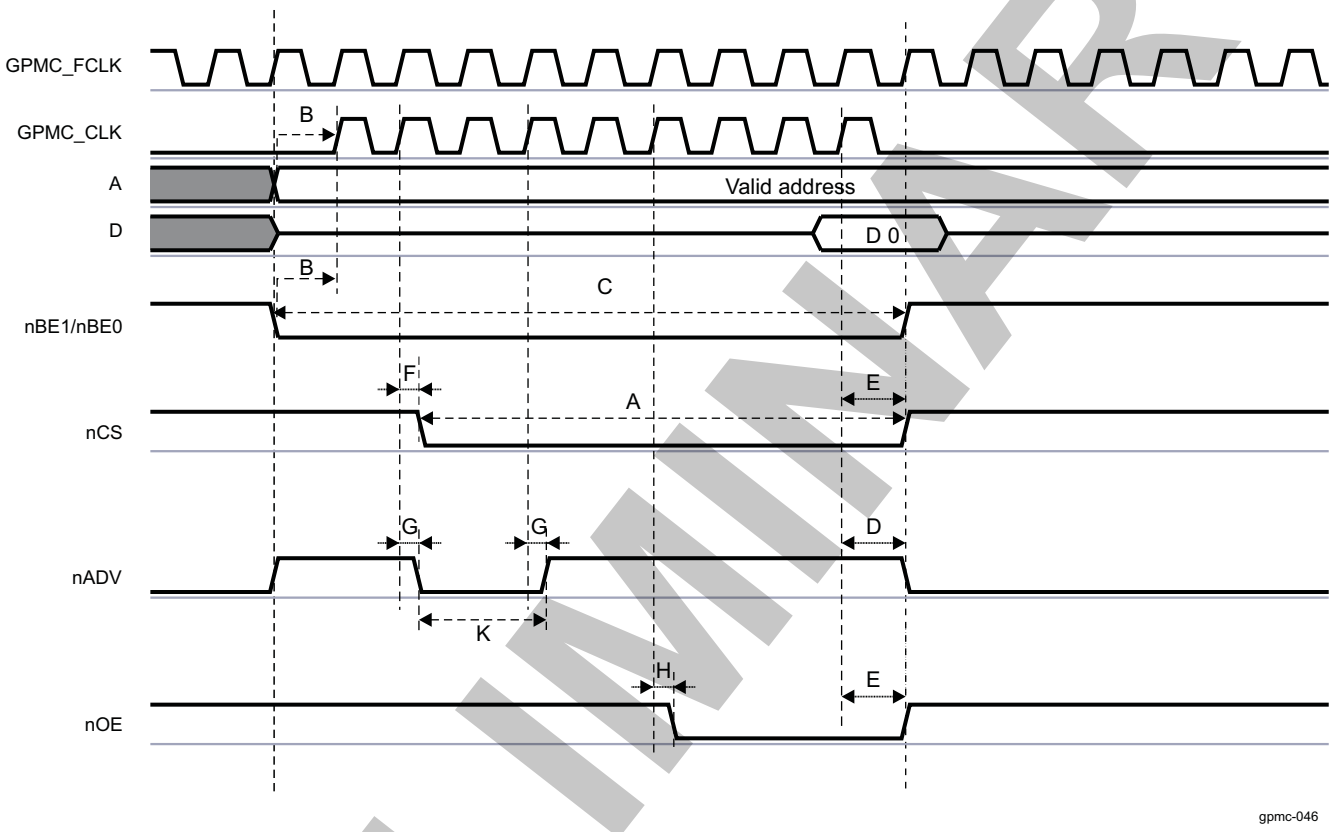
Copyright © 2013, Texas Instruments Incorporated

For gpmc_wait invalid to first data latching gpmc_clk edge:

- L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC_FCLK period + GPMC_CLK period

Figure 15-95 shows a simplified example of a synchronous NOR single read where formulas are associated with signal waves.

Figure 15-95. Synchronous NOR Single Read Simplified Example



15.4.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all the formulas to calculate asynchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode. Table 15-377 describes the asynchronous NOR formulas.

Table 15-377. Asynchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_ncs low
B	ns	Delay time – gpmc_ncs valid to gpmc_nadv_ale invalid
C	ns	Delay time – gpmc_ncs valid to gpmc_noe invalid (single read)
D	ns	Pulse duration – address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time – gpmc_ncs valid to gpmc_nwe valid
F	ns	Delay time – gpmc_ncs valid to gpmc_nwe invalid
G	ns	Address invalid duration between two successive R/W accesses
H	ns	Setup time – read data valid before gpmc_noe high
I	ns	Delay time – gpmc_ncs valid to gpmc_noe invalid (burst read)

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 15-377. Asynchronous NOR Formulas Description (continued)

Configuration Parameter	Unit	Description
J	ns	Delay time – address bus valid to gpmc_ncs valid
		Delay time – data bus valid to gpmc_ncs valid
		Delay time – gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_ncs valid
K	ns	Delay time – gpmc_ncs valid to gpmc_nadv_ale valid
L	ns	Delay time – gpmc_ncs valid to gpmc_noe valid
M	ns	Delay time – gpmc_ncs valid to first data latching edge
N	ns	Pulse duration – gpmc_nbe0_cle/gpmc_nbe1 valid time
O	ns	Delay time – gpmc_ncs valid to gpmc_nadv_ale valid

The configuration parameters are calculated through the following formulas. These formulas are not exhaustive.

- gpmc_ncs low pulse:
  For single read: A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: A = (CSRDOFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For single write: A = (CSWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst write: A = (CSWROFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
- gpmc_ncs valid to gpmc_nadv_ale invalid delay:
  For reading: B = ((ADVRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
  For writing: B = ((ADVWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- C = ((OEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- D = PAGEBURSTACCESSTIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- E = ((WEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- F = ((WEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- G = CYCLE2CYCLEDELAY * GPMC_FCLK period
- H = ((OEOFFTIME – ACCESSTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * OEEXTRADELAY) * GPMC_FCLK period
- I = ((OEOFFTIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period, where N = page burst access number
- J = (CSONTIME * (TIMEPARAGRANULARITY + 1) + 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- K = ((ADVONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- L = ((OEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- M = ((ACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) – 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- gpmc_nbe0_cle/gpmc_nbe1 pulse:
  For single read: N = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: N = (RDCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For burst write: N = (WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) *

PRELIMINARY

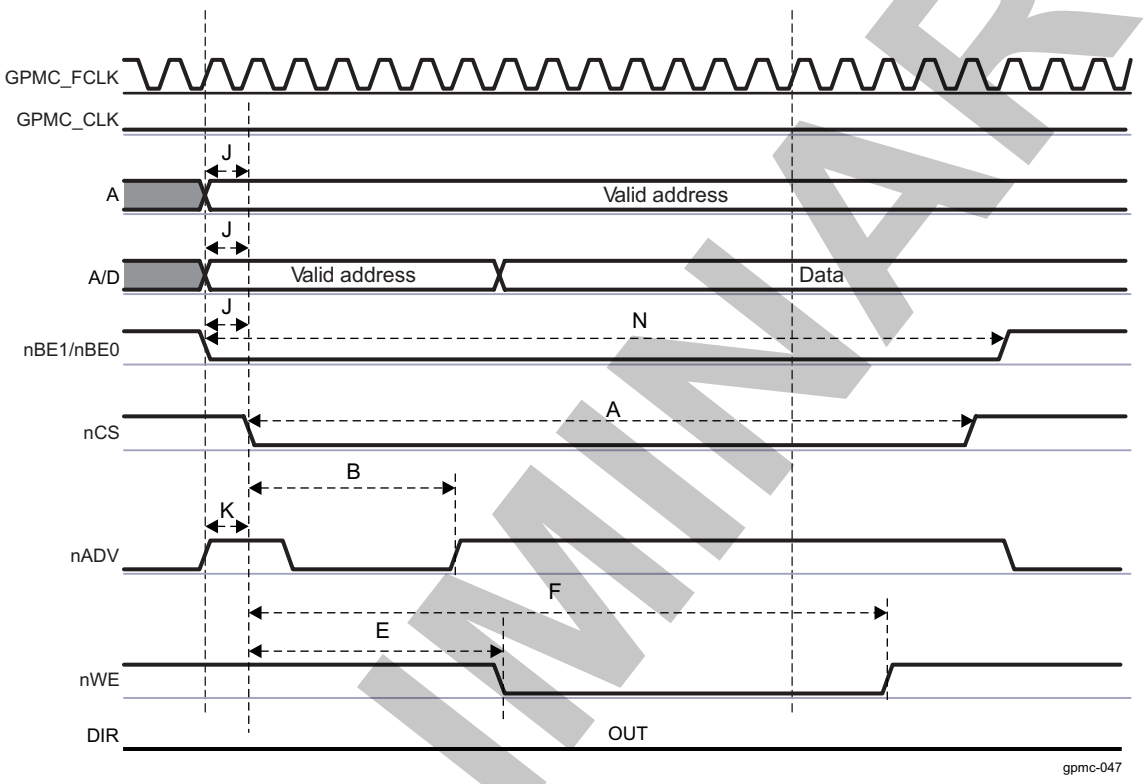
Copyright © 2013, Texas Instruments Incorporated

(TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number

- O = ((WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period

Figure 15-96 shows a simplified example of an asynchronous NOR single write where formulas are associated with signal waves.

Figure 15-96. Asynchronous NOR Single Write Simplified Example



NOTE: Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

15.4.6.1 How to Set GPMC Timing Parameters for Typical Accesses

15.4.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8- or 16-bit-wide memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples describe how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

15.4.6.1.2 Typical GPMC Setup

Table 15-378 lists some of the I/Os of the GPMC module.

Table 15-378. GPMC Signals

Signal Name	I/0	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk(1)	O	External clock provided to the external device for synchronous operations
gpmc_a[25:16]	O	Address
gpmc_ad[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_ncsx	O	Chip-select (where x = 0, or 1)
gpmc_nadv_ale	O	Address valid enable
gpmc_noe_nre	O	Output enable (read access only)
gpmc_nwe	O	Write enable (write access only)
gpmc_wait[2:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

(1) This output signal is also used as a retiming input. During synchronous operation, the INPUTENABLE bit of the CONTROL_CORE_PAD0_GPMC_NWP_PAD1_GPMC_CLK register must be set to 1.

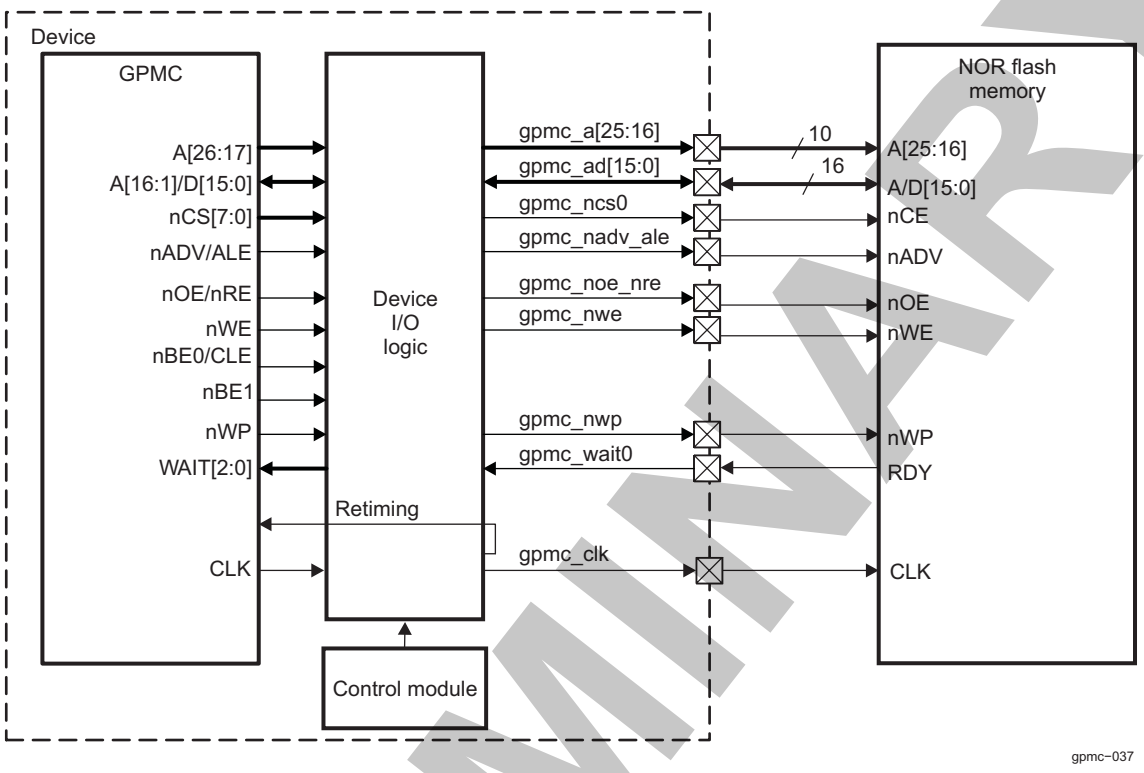
Figure 15-97 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 15-97. GPMC Connection to an External NOR Flash Memory



The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

15.4.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 15-379 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-380 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-98 shows the synchronous burst read access.

Table 15-379. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6

Table 15-379. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle (T = 9,615 ns). The read access time between two bursts of data is tBACC = 5.2 ns. Therefore, data setup time is a clock period – tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 15-380. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	–	–	–	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94.03: (9,615 + 80 + 4,415)	10: roundmax (94.03 / 9,615)	ACCESSTIME = 0x0A
PageBurst AccessTime	roundmax (tBACC)	roundmax (5.2)	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	Access time + max (tCEZ, tOEZ)	101.03: (94.03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC (1)	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC (2)	12	2	ADVRDOFFTIME = 0x02
OeOnTime (3)	(ClkActivationTime + tACH) < OeOnTime (ClkActivationTime + tIACC)	–	3, for instance	OEONTIME = 0x3
OeOffTime	RdCycleTime	–	11	OEOFFTIME = 0x0B

(1) The external clock provided to the NOR flash is not yet available.
(2) AdvRdOffTime – AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.
(3) OeOnTime must ensure that addresses are available. It must not exceed the availability of the first burst of data.

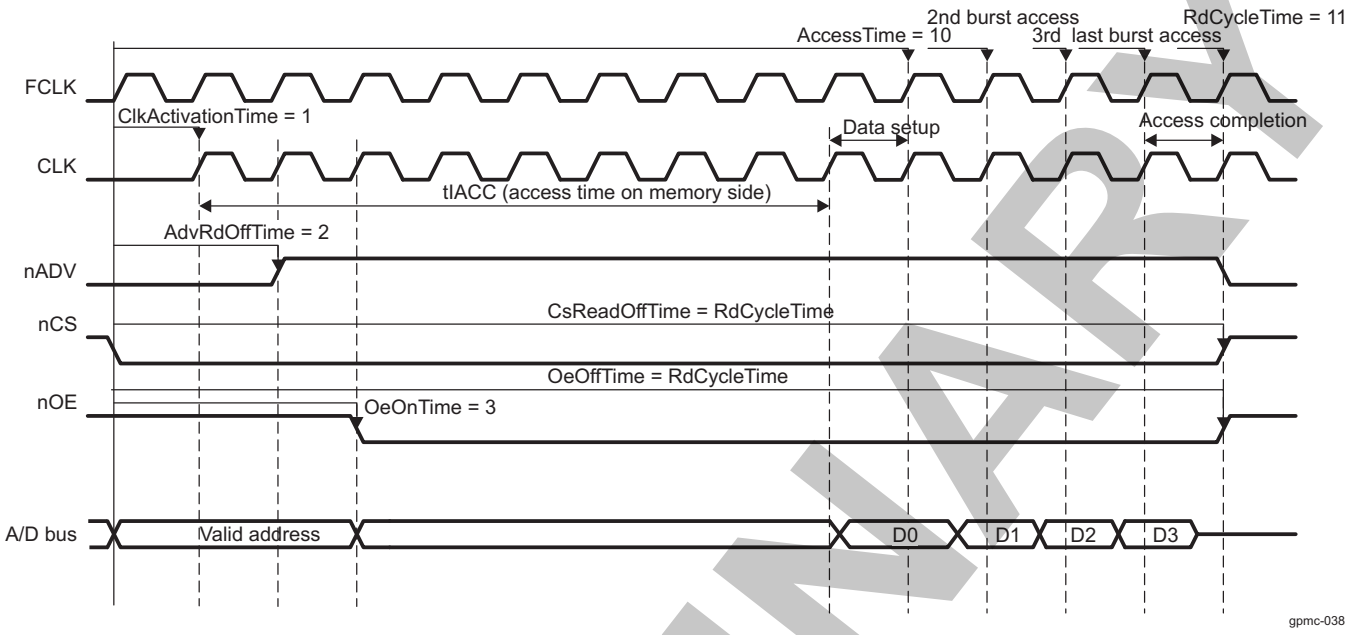
Figure 15-98. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)



15.4.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 15-381 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-382 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-99 shows the asynchronous read access.

Table 15-381. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 clock cycle + tOEZ:

1. On the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 15-381: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

   The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.
2. To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
3. There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is one clock cycle (that is, AccessTime + 1).

PRELIMINARY

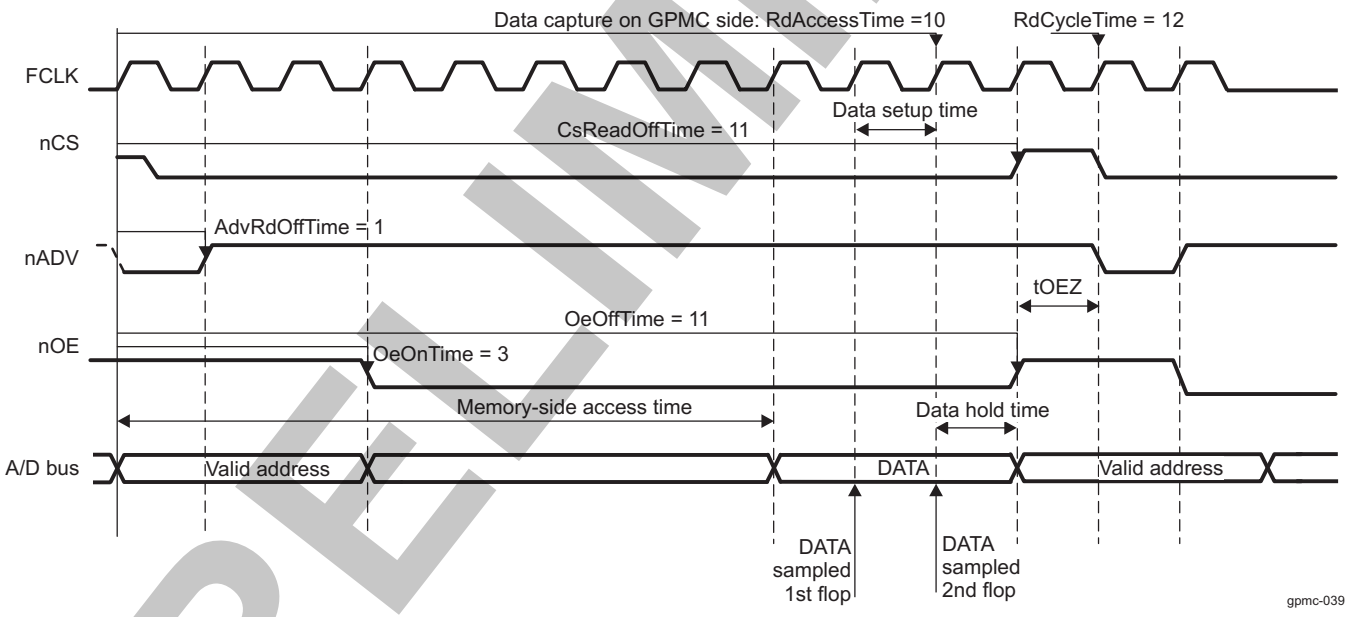
Copyright © 2013, Texas Instruments Incorporated

4. To complete the access, nOE/nCS signals are driven to High-Z. AccessTime + 1 + tOEZ is the read cycle time.
5. Addresses can now be relatched and a new read cycle begun.

Table 15-382. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
AccessTime	round max (tCE)	80	10	ACCESSTIME = 0x0A
PageBurstAccess Time	N/A (single access)			
RdCycleTime	AccessTime + 1cycle + tOEZ	96, 615	12	RDCYCLETIME = 0x0C
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	AccessTime + 1 cycle	89, 615	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0X1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 0x3
OeOffTime	AccessTime + 1cycle	89, 615	11	OEOFFTIME = 0x0B

Figure 15-99. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)



15.4.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 15-384 shows how to calculate timings for the GPMC using the memory parameters.

Table 15-383 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 15-100 shows the synchronous burst write access.

PRELIMINARY

Table 15-383. AC Characteristics for Asynchronous Single Write (Memory Side)

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccesCompletion, the GPMC requires one cycle of data hold time (nCS deassertion).

Table 15-384. GPMC Timing Parameters for Asynchronous Single Write

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime	N/A (asynchronous mode)			
AccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime	N/A (single access)			
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x05

15.4.6.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

15.4.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or devices, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit-wide asynchronous or synchronous memory or device (only 8-bit: nonburst device)
- 16-bit address and data-multiplexed NOR flash devices (pSRAM, OneNAND™, etc.)
- 8- and 16-bit NAND flash devices

NOTE: Nonmultiplexed NOR flash devices are supported by the GPMC, but their use is highly limited. Because only 10 address pins are available on the GPMC interface, the maximum device size supported is 2KiB.

15.4.6.2.1.1 Memory Pin Multiplexing

This section describes the interfacing differences of the GPMC supported memories.

Table 15-385. Supported Memories Interfaces

Function	16-Bit Address/ Data-Multiplexed pSRAM or NOR Flash [1]	OneNAND	16-Bit NAND	8-Bit NAND
gpmc_a[25]	A26			
gpmc_a[24]	A25			
gpmc_a[23]	A24			
gpmc_a[22]	A23			
gpmc_a[21]	A22			
gpmc_a[20]	A21			
gpmc_a[19]	A20			
gpmc_a[18]	A19			
gpmc_a[17]	A18			
gpmc_a[16]	A17			
gpmc_ad[15]	D15 or A16		IO15	
gpmc_ad[14]	D14 or A15		IO14	
gpmc_ad[13]	D13 or A14		IO13	
gpmc_ad[12]	D12 or A13		IO12	
gpmc_ad[11]	D11 or A12		IO11	
gpmc_ad[10]	D10 or A11		IO10	
gpmc_ad[9]	D9 or A10		IO9	
gpmc_ad[8]	D8 or A9		IO8	
gpmc_ad[7]	D7 or A8		IO7	
gpmc_ad[6]	D6 or A7		IO6	
gpmc_ad[5]	D5 or A6		IO5	
gpmc_ad[4]	D4 or A5		IO4	
gpmc_ad[3]	D3 or A4		IO3	
gpmc_ad[2]	D2 or A3		IO2	
gpmc_ad[1]	D1 or A2		IO1	
gpmc_ad[0]	D0 or A1		IO0	

(1) Addresses seen from the device side. When interfacing to the external device, A1 is connected to the memory A0, A2 to the memory A1, and so on.

gpmc_wait1	WAIT1		R/nB1	
gpmc_wait2	WAIT2		R/nB2	

15.4.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device; that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density NAND is best suited to devices that require high capacity data storage, such as pictures, music, and data files. NAND nonvolatility makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 15-386 summarizes the NAND interface signals level applied to external device or memories.

Table 15-386. NAND Interface Bus Operations Summary

Bus Operation	CLE	ALE	nCE	nWE [1]	nRE [1]	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H [2]	H [2]	H [2]	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Standby	x	x	H	x	x	H/L [3]

(1) RE stands for rising edge; FE stands for falling edge
(2) Can be nCE high, or WE and nRE high.
(3) nWP must be biased to CMOS high or CMOS low for standby

15.4.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; that is, it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it also has slow write and erase functions when compared to the NAND architecture.

Table 15-387 summarizes the level of the NOR interface signals applied to external devices or memories.

Table 15-387. NOR Interface Bus Operations Summary

Bus Operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

15.4.6.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

OneNAND is a high-density, low-power memory device. OneNAND is based on single- or multilevel-cell NAND core with SRAM and logic. It interfaces as a synchronous NOR flash and has synchronous write capability. It reads faster than conventional NAND and writes faster than conventional NOR flash. Hence, it is appropriate for mass storage and code storage.

pSRAM (pseudo-static random access memory) is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash. It also has synchronous write capability.

15.4.6.2.1.5 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, 16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4, 8, 16 Word16)
- Synchronous read burst access with wrap capability (4, 8, 16 Word16)

15.4.6.2.2 GPMC Features and Settings

The features and settings of the GPMC are:

- Supported device type: Up to four NAND or NOR protocol external memories or devices
- Operating voltage: 1.8 V
- Maximum GPMC addressing capability: 512MiB divided into eight chip-selects
- Maximum supported memory size: 256MiB (must be a power-of-two)
- Minimum supported memory size: 16MiB (must be a power-of-two). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8, 16 bits wide
- Burst and page access: burst of 4, 8, 16 Word16
- Supports bus keeping
- Supports bus turnaround

15.4.7.2 GPMC Register Descriptions

NOTE: All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to GPMC_NAND_DATA_i register, are little-endian. If the GPMC_NAND_DATA_i register location is accessed, the endianness is access-dependent.

In this section i corresponds to the chip-select number, where i = 0 to 7.

Table 15-390. GPMC_REVISION

Address Offset	0x0000 0000		
Physical Address	0x5000 0000	**Instance**	GPMC
Description	This register contains the IP revision code.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP revision	R	TI internal data

Table 15-392. GPMC_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x5000 0010	**Instance**	GPMC
Description	This register controls the various parameters of the interconnect.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																											IDLEMODE		RESERVED	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0000000
4:3	IDLEMODE	0x0: Force-idle. An idle request is acknowledged unconditionally. 0x1: No-idle. An idle request is never acknowledged. 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module. 0x3: Do not use.	RW	0x0
2	RESERVED	Write 0 for future compatibility Read returns 0.	RW	0x0
1	SOFTRESET	Software reset. Set this bit to 1 triggers a module reset. This bit is automatically reset by hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0x0

15.5 Error Location Module

15.5.1 Error Location Module Overview

Nonmanaged NAND flash memories can be dense and nonvolatile in their own nature, but error-prone. When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the software that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

15.5.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

15.5.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. The microprocessor unit (MPU) can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 15-101 shows the integration of the ELM subsystem in the device.

Figure 15-101. ELM Integration

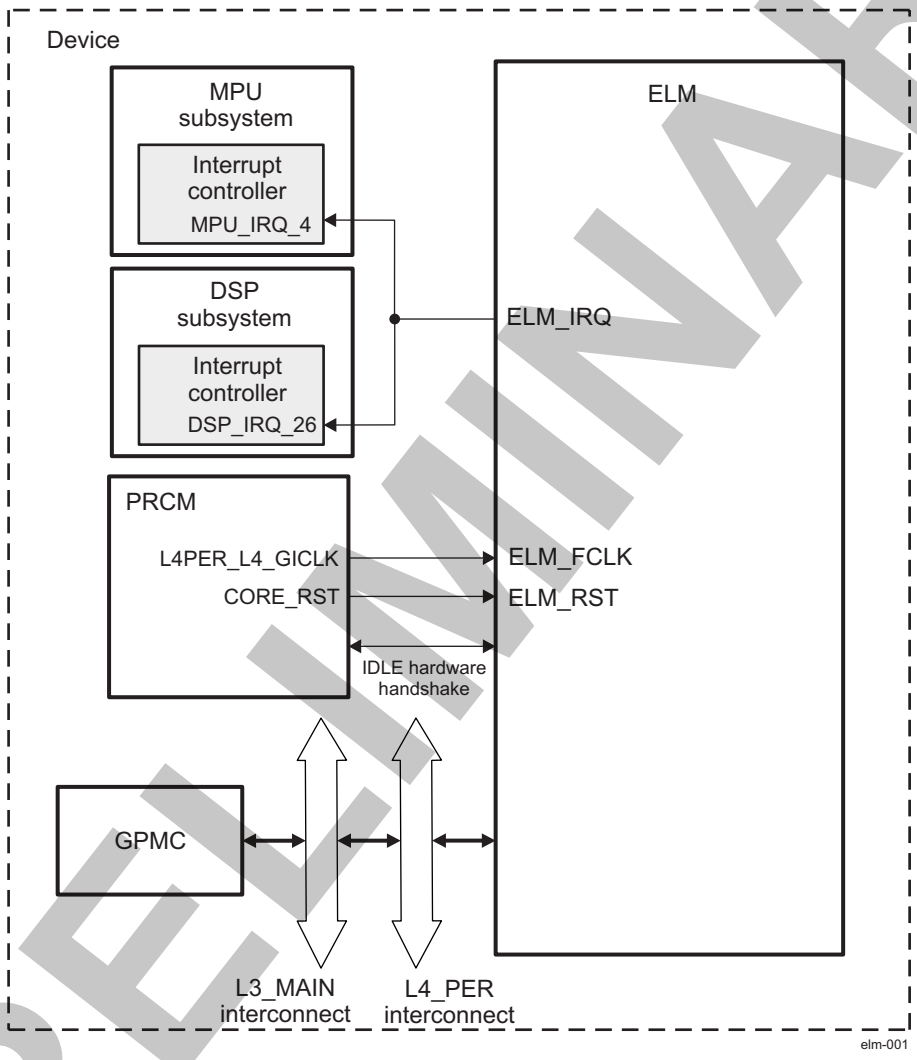

Table 15-462 through Table 15-464 summarize the integration of the module in the device.

15.5.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

15.5.3.1 ELM Software Reset

To perform a software reset, set the ELM_SYSCONFIG[1] SOFTRESET bit to 1. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

15.5.3.2 ELM Power Management

Table 15-465 describes the power-management features available to the ELM.

NOTE:

- For information about source clock gating and a description of the sleep/wake-up transitions, see the Section 3.6.8, *CD_L4_PER Clock Domain*, in Section 3.1.1, *Power, Reset, and Clock Management*.
- For a general description of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.6, *Clock Management Functional Description*, in Section 3.1.1, *Power, Reset, and Clock Management*

Table 15-465. Local Power-Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG[4:3] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY	The clock can be switched off or maintained during the wake-up period.
Master standby modes	N/A	
Global wake-up enable	N/A	
Wake-up sources enable	N/A	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits. For a description of the ClockActivity feature, see Section 3.1.1, *Power, Reset, and Clock Management*.

15.5.3.3 ELM Interrupt Requests

Table 15-466 lists the event flags, and their masks, that can cause module interrupts.

Table 15-466. Events

Event Flag	Event Mask	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	Error-location interrupt for syndrome polynomial 0

15.5.3.4 Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL bit field defines the error-correction level used (4-,8-, or 16-bit error correction). The ELM_LOCATION_CONFIG[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

Software can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits (i is the syndrome polynomial number, where i = 0 to 7) are reset, continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently. Results for a syndrome can be retrieved and acknowledged at any time, regardless of the status of the other seven processing

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

contexts.

- Page mode: Syndrome polynomials are grouped into atomic entities: only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (where i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

Software initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1, where i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers (where i = 0 to 7) are not reset. Software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

15.5.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i (where i = 0 to 7) are not updated.

In all other cases, the engine goes through the entire error-location process. Each time an error location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION bit field; the second is logged in the ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION bit field, and so on.

Table 15-467 describes the ELM_LOCATION_STATUS_i value decoding.

Table 15-467. ELM_LOCATION_STATUS_i Value Decoding

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependent

15.5.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (where i = 0 to 7) for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit (where i = 0 to 7) is set. The processing exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION bit fields. Software must read only valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. Software must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, software must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by setting it to 1. Other status bits must be set to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bits. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

NOTE: Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bits (where i = 0 to 7) are processed as usual, but are essentially ignored. Software must manually poll the ELM_IRQSTATUS bits to check for their status.

15.5.4 ELM Basic Programming Model

15.5.4.1 ELM Low-Level Programming Model

15.5.4.1.1 Processing Initialization

Table 15-468. ELM Processing Initialization

Step	Register/Bit Field/Programming Model	Value

15.5.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. Table 15-469 and Table 15-470 describe the processing completion for continuous and page modes, respectively.

Table 15-469. ELM Processing Completion for Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. Software must correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x0) and after the exit status register check (ELM_LOCATION_STATUS_i).

Table 15-470. ELM Processing Completion for Page Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependent.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	

PRELIMINARY

	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

15.5.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM is programmed for an 8-bit error-correction capability in continuous mode (see Table 15-471). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a nonzero polynomial syndrome is reported from the GPMC (polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 15-471. Use Case: Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x1

Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 0)	0x4

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 15-471. Use Case: Continuous Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1AF
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x426
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x775
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, and then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 15-472 are given in decimal format.

Table 15-472. 16-Bit NAND Sector Buffer Address Map

NAND Memory Address	Message Bit Addresses in Memory Word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

50	3415	3414	3413	3412	3411	3410	3409	3408	3423	3422	3421	3420	3419	3418	3417	3416
...																
255	135	134	133	132	131	130	129	128	143	142	141	140	139	138	137	136
256	119	118	117	116	115	114	113	112	127	126	125	124	123	122	121	120
257	103	102	101	100	99	98	97	96	111	110	109	108	107	106	105	104
258	87	86	85	84	83	82	81	80	95	94	93	92	91	90	89	88
259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and flip this bit. The same process must be repeated for all detected errors.

15.5.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode (see Table 15-473). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189

	ELM_SYNDROME_FRAGMENT_5_i (where i = 0)	0x12ADDB5A
	ELM_SYNDROME_FRAGMENT_6_i (where i = 0)	0xE8B0
Set the input syndrome polynomial 1.	ELM_SYNDROME_FRAGMENT_0_i (where i = 1)	0xE5F935EB
	ELM_SYNDROME_FRAGMENT_1_i (where i = 1)	0x79C6BA10
	ELM_SYNDROME_FRAGMENT_2_i ((where i = 1)	0xBE093336
	ELM_SYNDROME_FRAGMENT_3_i (where i = 1)	0x0948DF08
	ELM_SYNDROME_FRAGMENT_4_i (where i = 1)	0xC22E6669
	ELM_SYNDROME_FRAGMENT_5_i (where i = 1)	0x49A0D932
	ELM_SYNDROME_FRAGMENT_6_i (where i = 1)	0xBAD0
Set the input syndrome polynomial 2.	ELM_SYNDROME_FRAGMENT_0_i (where i = 2)	0x60BA3189
	ELM_SYNDROME_FRAGMENT_1_i (where i = 2)	0x1579EF7D
	ELM_SYNDROME_FRAGMENT_2_i (where i = 2)	0x54556EA0
	ELM_SYNDROME_FRAGMENT_3_i (where i = 2)	0xA6498FEE
	ELM_SYNDROME_FRAGMENT_4_i (where i = 2)	0xEC3697FA
	ELM_SYNDROME_FRAGMENT_5_i (where i = 2)	0xB86ABCD5
	ELM_SYNDROME_FRAGMENT_6_i (where i = 2)	0x69D9
Set the input syndrome polynomial 3.	ELM_SYNDROME_FRAGMENT_0_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_1_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_2_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_3_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_4_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_5_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_6_i (where i = 3)	0x0
Initiates the computation process for syndrome polynomial 0	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1
Initiates the computation process for syndrome polynomial 1	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 1)	0x1
Initiates the computation process for syndrome polynomial 2	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 2)	0x1
Initiates the computation process for syndrome polynomial 3	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 3)	0x1

Table 15-473. Use Case: Page Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial 0, 1, 2, and 3: Wait until the ELM_IRQ interrupt is generated or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Read the process exit status for syndrome polynomial 0: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the process exit status for syndrome polynomial 1: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 1)	0x1
Read the process exit status for syndrome polynomial 2: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 2)	0x1
Read the process exit status for syndrome polynomial 3: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 3)	0x1
Read the number of errors for syndrome polynomial 0: four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 0)	0x4
Read the number of errors for syndrome polynomial 1: two errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 1)	0x2
Read the number of errors for syndrome polynomial 2: one error detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 2)	0x1
Read the number of errors for syndrome polynomial 3: no errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 3)	0x0
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers:	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1FE
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x617
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x650
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xA83
Read the error-location bit addresses for syndrome polynomial 1 of the first two registers:	ELM_ERROR_LOCATION_0_i (where i = 1)	0x4
	ELM_ERROR_LOCATION_1_i (where i = 1)	0x1036
Read the errors location bit addresses for syndrome polynomial 2 of the first registers:	ELM_ERROR_LOCATION_0_i (where i = 1)	0x3E8
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

15.5.5.2.2 ELM Register Description

through describe the individual ELM registers.

Table 15-476. ELM_REVISION

Address Offset	0x0000 0000		
Physical Address	0x4807 8000	**Instance**	ELM
Description	This register contains the IP revision code. (A write or reset of to this register has no effect.)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP Revision (TI internal data)	R	0x-

Table 15-477. Register Call Summary for Register ELM_REVISION

Error Location Module

- ELM Register Summary: [0]

Table 15-478. ELM_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x4807 8010	**Instance**	ELM
Description	This register allows controlling various parameters of the OCP interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								CLOCKACTIVITYOCP	RESERVED			SIDLEMODE		RESERVED	SOFTRESET	AUTOGATING

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x000000
8	CLOCKACTIVITYOCP	OCP clock activity when module is in IDLE mode (during wake-up mode period) 0x0: OCP clock can be switched off. 0x1: OCP clock is maintained during wake-up period.	RW	0
7:5	RESERVED	Reserved	R	0x0
4:3	SIDLEMODE	Slave interface power management (IDLE req/ack control) 0x0: Force-idle. IDLE request is acknowledged unconditionally and immediately (Default *Dumb* mode for safety) 0x1: No-idle. IDLE request is never acknowledged. 0x2: Smart-idle. The acknowledgment to an IDLE request is given based on the internal activity. 0x3: Reserved - do not use	RW	0x2

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
2	RESERVED	Reserved	R	0
1	SOFTRESET	Module software reset This bit is automatically reset by hardware (during reads, it always returns 0). It has same effect as the OCP hardware reset. 0x0: Normal mode 0x1: Start soft reset sequence.	RW	0
0	AUTOGATING	Internal OCP clock gating strategy (no module visible effect other than saving power) 0x0: OCP clock is free-running. 0x1: Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.	RW	1

15.6 On-Chip Memory (OCM) Subsystem

15.6.1 OCM Subsystem Overview

There are two on-chip memories in the device.

- 5-KiB SAR random-access memory (RAM)
- 128-KiB level 3 (L3) static random-access memory (L3 OCM_RAM)

There are other on-chip memories inside other subsystems (MPU, DSP, IVA-HD, ABE, IPU) that are not described in the following sections. For more information about these memories, see each subsystem chapter.

15.6.2 OCM Subsystem Integration

Figure 15-102 shows the integration of the OCM subsystem to the device.

Figure 15-102. OCM Subsystem Integration to the Device

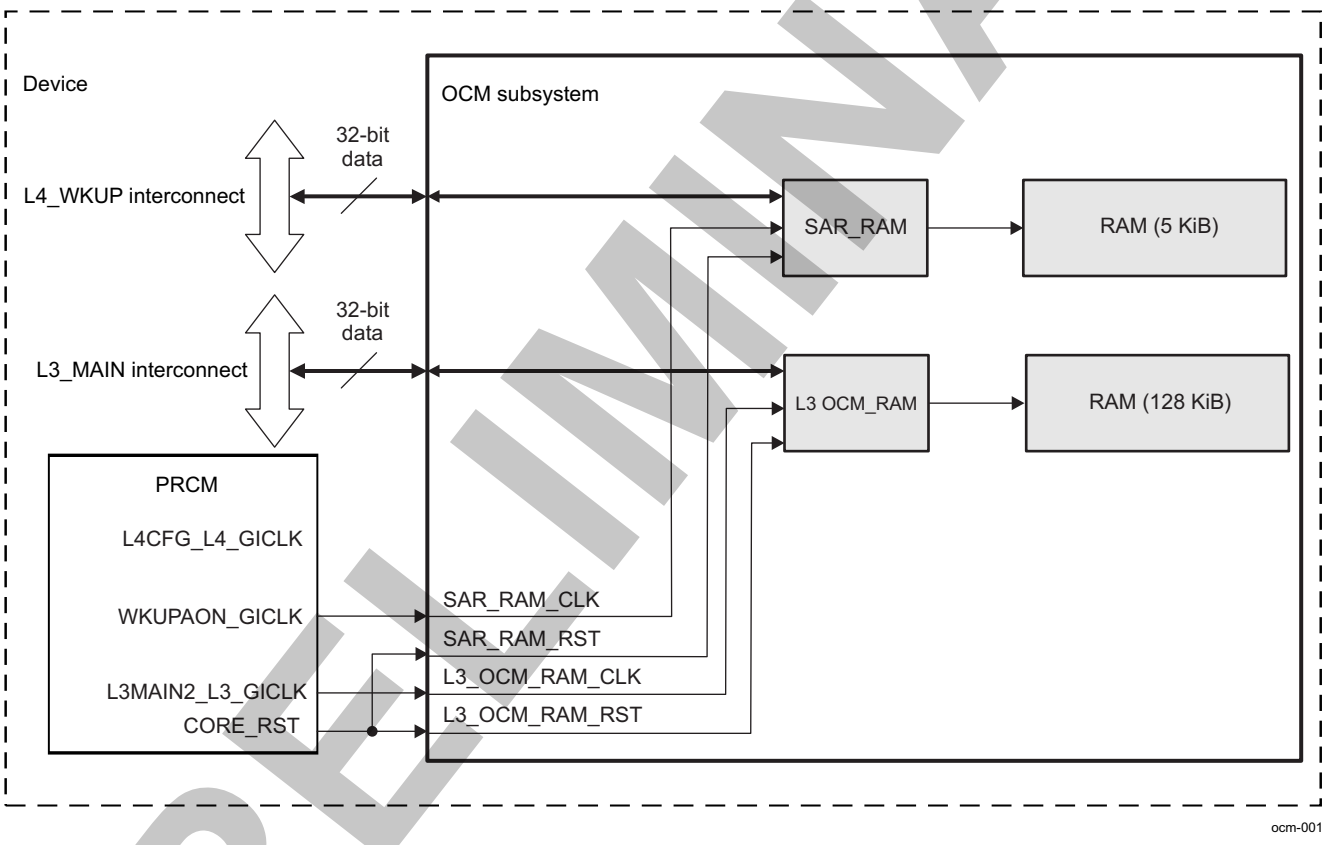

Table 15-538 and Table 15-539 summarize the integration of the module in the device.

15.6.3 OCM Subsystem Functional Description

15.6.3.1 SAR RAM

The on-chip SAR RAM contains 5 KiB and is mapped as two blocks. The SAR RAM is used by device ROM code to store the software booting configuration: a logical structure that allows the redefinition of the ROM code default settings when booting after a warm reset. The SAR RAM is mapped on the wake-up voltage domain.

The device-embedded SAR RAM has the following characteristics:

- Support for single-access transactions
  - Operates at full L4_PER interconnect clock frequency
  - 32-bit access per cycle

The SAR RAM space is at the following location:

- SAR space 1 (4 KiB): Starts at 0x4AE2 6000 and ends at 0x4AE2 6FFF
- SAR space 2 (1 KiB): Starts at 0x4AE2 7000 and ends at 0x4AE2 73FF

15.6.3.2 L3 OCM_RAM

The on-chip L3 OCM_RAM contains 128 KiB of RAM, partitioning is defined by the L3 firewall logic.

The device-embedded L3 OCM_RAM has the following characteristics:

- Support for single and burst access transactions:
  - Operates at full L3 interconnect clock frequency
  - Fully pipelined, one 32-bit access per cycle
- Restricted access support based on:
  - A region-based partitioning (see the L3 firewall description)
  - The module owner of the access, with respect to its read and write permissions to that region
  - The transaction attributes of the access, with respect to the region permission properties. For more information, see Section 14.2.1, *L3 _MAIN Interconnect*.

System DMA

This chapter describes the system direct memory access (DMA_SYSTEM) module.

NOTE: Some of the system DMA features, primarily those concerning the device I/O pads and the system DMA integration, are not available in all OMAP54xx devices.

For details, see , *OMAP543x Family and Device Identification*, in Chapter 1, *Introduction*, and the corresponding TRM appendix and device data manual.

16.1 DMA_SYSTEM Module Overview

The system direct memory access (DMA_SYSTEM) module, also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The DMA controller includes the following main features:

- Data transfer support in either direction between:
  - Memory and memory
  - Memory and peripheral device
- 32 logical DMA channels supporting:
  - Multiple concurrent transfers
  - Independent transfer profile for each channel
  - 8-bit, 16-bit, or 32-bit data element transfer size
  - Software-triggered or hardware-synchronized transfers
  - Flexible source and destination address generation
  - Burst read and write - max burst size is 16
  - Chained multiple-channel transfers
  - Endianism conversion
  - Draining
  - Linked-list support for descriptor types 1, 2, and 3
- First-come, first-serve DMA scheduling with fixed priority
- Up to 127 DMA requests
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- FIFO depth: 256 × 64-bit
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support
- Implementation of retention flip-flops (RFFs) to support dynamic power switching (DPS) between system power modes without MPU involvement. For more information about DPS, see Section 3.1.2.3, *Dynamic Power Switching*, in Chapter 3, *Power, Reset and Clock Management*.

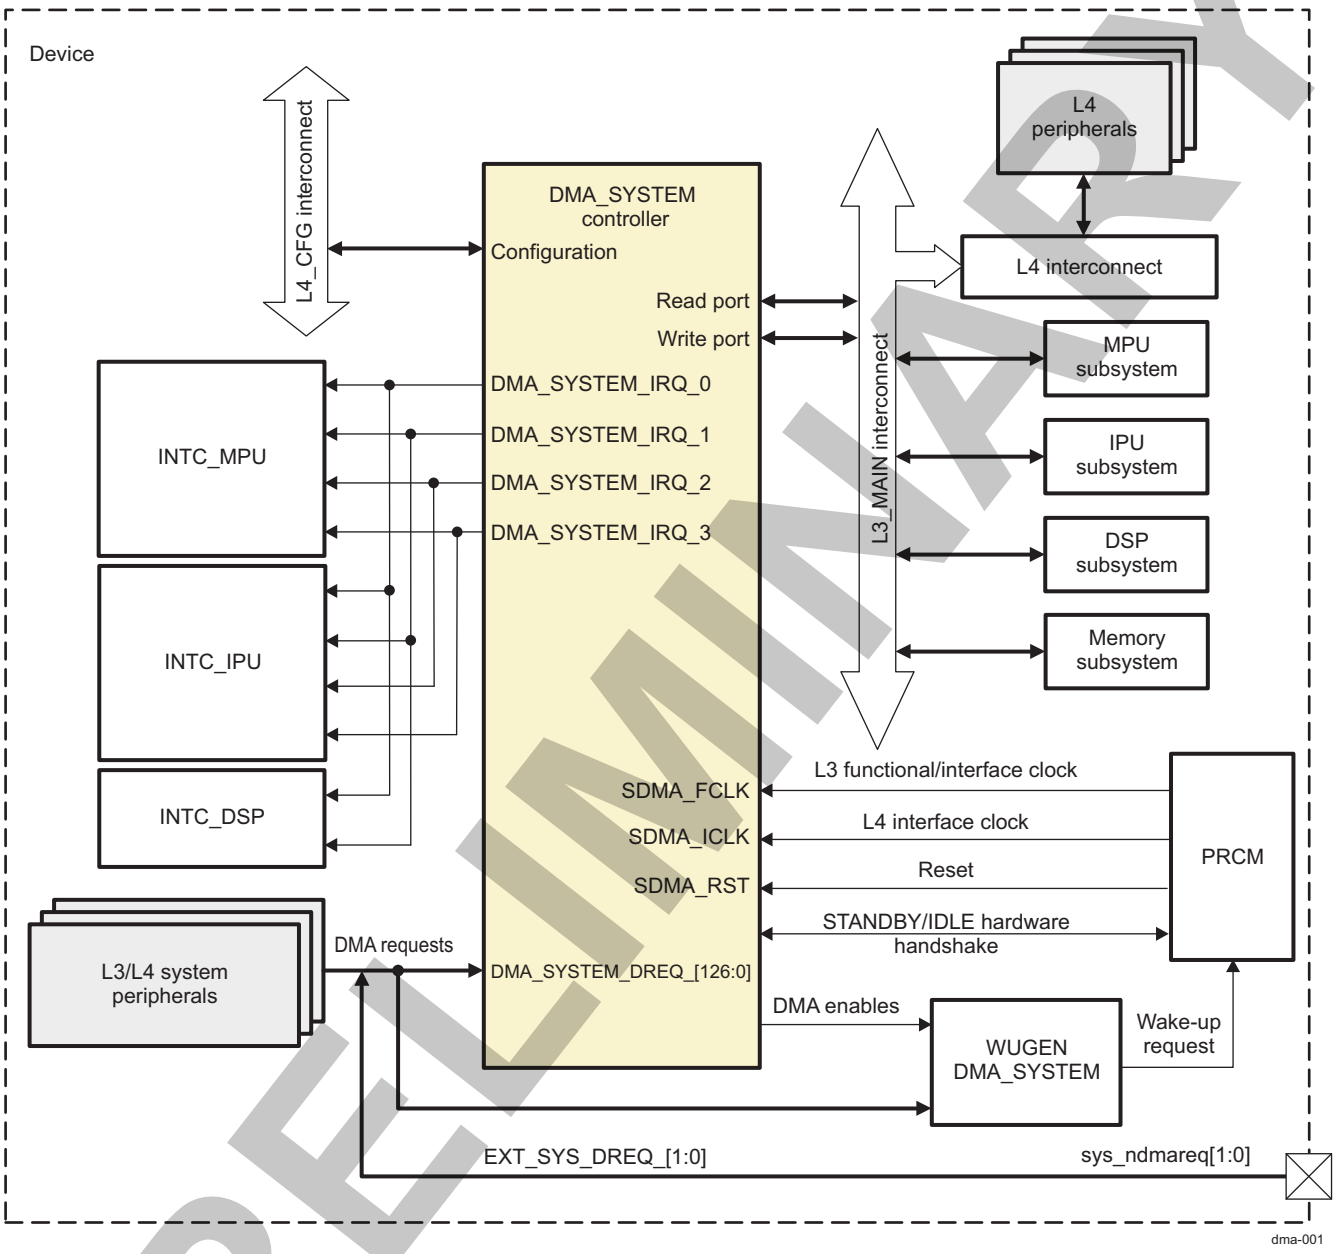
Figure 16-1 shows an overview of the DMA_SYSTEM module.

Figure 16-1. DMA_SYSTEM Overview



The DMA_SYSTEM module has three ports: one read, one write, and one configuration port, and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports, which are multithreaded (two threads for the write port and four threads for the read port); this means that each transaction is flagged by a thread ID (0, 1, 2, or 3) in the request direction and in the response direction. This allows the read port to have four outstanding requests at a time. The write port has two threads budget available.

The MPU (or DSP) configures the DMA_SYSTEM through the L4_CFG interconnect.

16.2 DMA_SYSTEM Controller Environment

The DMA_SYSTEM controller supports external DMA requests through the sys_ndmareq[1:0] pins (see Table 16-1). A logical channel can be configured to respond to an external synchronization request.

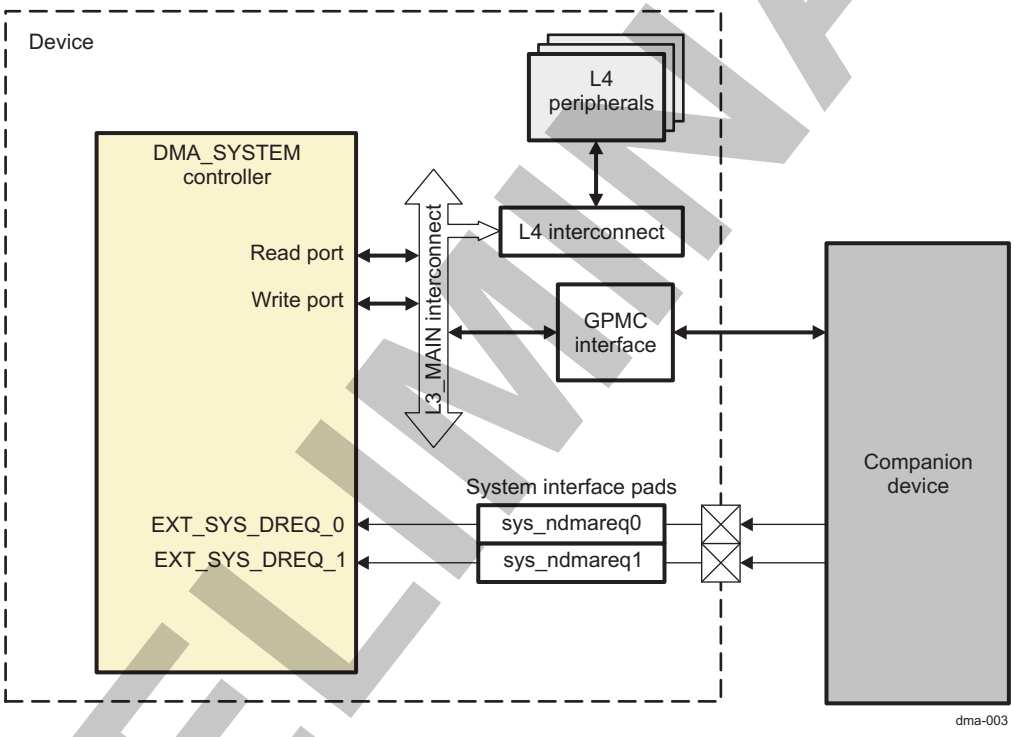
Table 16-1. External DMA_SYSTEM Request Signals

Pin Name	Signal Name	I/O[1]	Description	Module Reset Value
sys_ndmareq0	EXT_SYS_DREQ_0	I	External DMA request 0 (system expansion)	Z
sys_ndmareq1	EXT_SYS_DREQ_1	I	External DMA request 1 (system expansion)	Z

(1) I = Input, O = Output

Figure 16-2 shows an example of how to use the external hardware DMA request pins in the DMA_SYSTEM environment.

Figure 16-2. Example of External DMA Requests Use



An external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the two signal lines to pins, see Chapter 18, *Control Module*.

All 127 DMA request lines are transition sensitive.

For a transition-sensitive DMA request (see Figure 16-3), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (deasserted) for greater than one clock cycle (DMA_L3_GICLK):

- When the deassertion time is less than one clock cycle, the DMA_SYSTEM may not detect the deassertion.
- When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.
- When the channel is enabled two cycles after the DMA request is disabled, the channel does not detect the DMA request.

Table 16-3. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
DMA_SYSTEM	SDMA_FCLK	DMA_L3_GICLK	PRCM	Functional clock for all internal logic and for the two master read and write ports. For information about the power, reset, and clock management (PRCM) clock gating and management, see Chapter 3, *Power, Reset, and Clock Management*.
	SDMA_ICLK	DMA_L4_GICLK		Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see Chapter 3, *Power, Reset, and Clock Management*.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
DMA_SYSTEM	SDMA_RST	DMA_RET_RST	PRCM	Hardware retention reset. It initializes all internal logic of the DMA_SYSTEM module, all global registers, and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see Chapter 3, *Power, Reset, and Clock Management*.

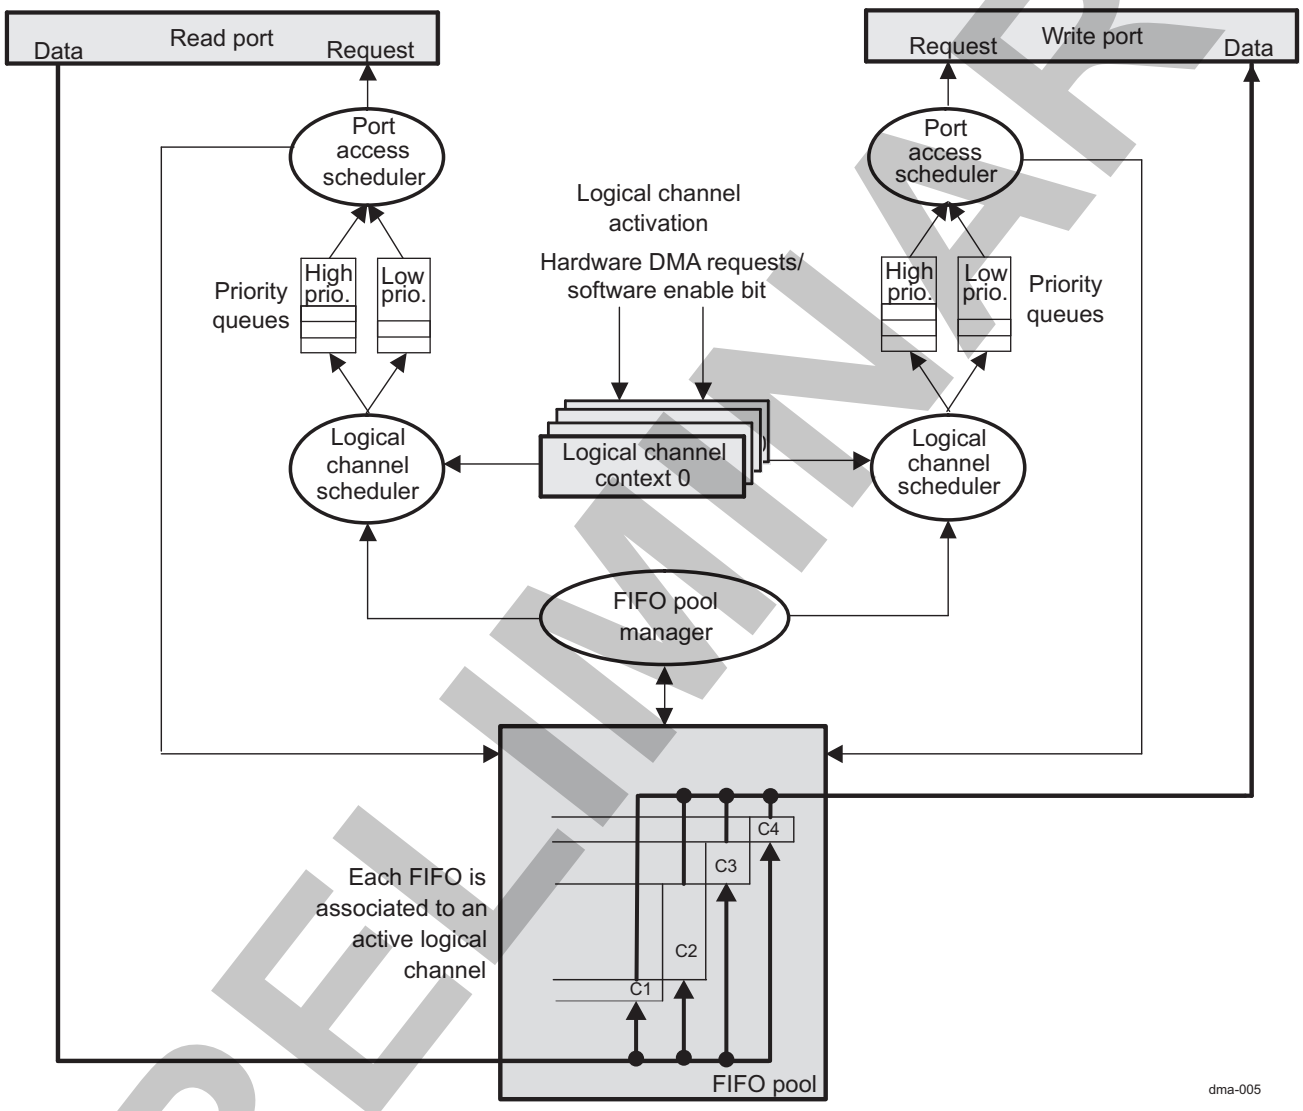
16.4 DMA_SYSTEM Functional Description

The DMA_SYSTEM module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 16-5 shows the DMA_SYSTEM controller top-level block diagram.

Figure 16-5. DMA_SYSTEM Controller Top-Level Block Diagram



16.4.1 DMA_SYSTEM Controller Power Management

Table 16-6 describes power-management features available for the DMA_SYSTEM controller.

NOTE:

- For information about source clock gating and sleep/wake-up transitions, see Section 3.1.1.1.2, *Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
- For a description of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 16-6. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	DMA4_OCP_SYSCONFIG[0] AUTOIDLE bit	This bit allows local power optimization inside the module by gating the SDMA_ICLK clock upon the interface activity.
Slave idle modes	DMA4_OCP_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	DMA4_OCP_SYSCONFIG[9:8] CLOCKACTIVITY bit field	For configuration details, see Table 16-7.
Master standby modes	DMA4_OCP_SYSCONFIG[13:12] MIDLEMODE bit field	Force-standby, no-standby, and smart-standby modes are available.
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

Table 16-7. Clock Activity Settings

SDMA_CLOCKACTIVITY Values	Clock State When Module is in IDLE State	
	SDMA_ICLK	SDMA_FCLK
00	Off	Off
10	Off	On
01	On	Off
11	On	On

CAUTION

Because the PRCM module cannot read CLOCKACTIVITY settings through hardware, software must ensure consistent programming between the SDMA_CLOCKACTIVITY and DMA_SYSTEM clock PRCM control bits. For a description of the ClockActivity feature, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

16.4.2 DMA_SYSTEM Controller Interrupt Requests

DMA4 has four interrupt lines (Lj, where j = 0, 1, 2, 3). Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. Software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- The DMA4_IRQSTATUS_Lj CH_31_0_Lj field shows the status of the different sources of interrupt. If the DMA4_IRQENABLE_Lj bit is 1, channel *i* is the source of interrupt in line *j*. In contrast to the DMA4_CSRi registers, the DMA4_IRQSTATUS_Lj registers are updated regardless of the corresponding bits in the DMA4_IRQENABLE_Lj registers.
- The DMA4_IRQENABLE_Lj CH_31_0_Lj_EN field masks/unmasks the channel interrupt. If the DMA4_IRQENABLE_Lj bit is set to 0, channel interrupt *i* of the line *j* is masked.

Each logical channel can generate a number of different interrupt events when enabled (that is, set to 1) in the DMA4_CICRi register. Each status bit is updated in the DMA4_CSRi register only when the corresponding enable bit is enabled in the DMA4_CICRi register.

To determine an interrupt source when an interrupt rises on an interrupt line L*j*:

- Identify the channel (LCH*i*) generating the interrupt.

  Read DMA4_IRQSTATUS_Lj.LCH*i* (LCH0 to LCH31). If LCH*i* = 1, channel *i* is the originator of the interrupt.
- Identify the interrupt event.

  Read the LCH*i* DMA4_CSRi. For example, if the drop event (the DMA4_CSRi[1] DROP bit) is 1, a

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

request collision will occur.

The interrupt event status bit in the DMA4_CSRi register is immediately reset after it is written to 1.

The interrupt status bit in the DMA4_IRQSTATUS_Lj register is cleared after it is written to 1.

16.4.2.1 Interrupt Generation

The DMA_SYSTEM module has four interrupt request output lines, DMA_SYSTEM_IRQ_0 to DMA_SYSTEM_IRQ_3. One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in Table 16-8 occurs.

Table 16-8. Logical DMA Channel Events

Event	Description
End of packet	A packet transfer completed.
End of block	A block transfer completed.
End of frame	A frame transfer completed.
End of super block	A super block transfer completed.
Half of frame	Half of the current frame transferred.
Start of last frame	The first element of the last frame transferred.
Transaction error	A transaction error is returned by the interconnect in either the read or write port.
Address error	An attempt was made to perform a DMA access to an address not aligned on an ES boundary. Condition to occur: if DMA4_CEN[23:0] CHANNEL_ELMNT_NBR = 0x000000 or DMA4_CFN[15:0] CHANNEL_FRAME_NBR = 0x0000 or DMA4_CSDP[1:0] DATA_TYPE = 0x3.
Supervisor transaction error	An error occurred, for example, when an unauthorized initiator (that is not a supervisor) tries to use a supervisor transfer.
Drain end	Drain is completed (DMA4_CCRi[10] WR_ACTIVE becomes 0).
Drop error	A drop event interrupt is generated when a DMA request is being serviced while a second one is asserted and a third one arrives before the second DMA request is serviced.

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the DMA4_IRQENABLE_Lj register (where *j* is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel DMA4_CICRi register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the DMA4_IRQSTATUS_Lj register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel DMA4_CSRi register.

16.4.3 Logical Channel Transfer Overview

As Figure 16-5 shows, the DMA_SYSTEM module has one read port and one write port operating independently of one another. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization

  A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.
- Logical channel activation

  A logical channel becomes active as follows:
  - For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA request line is asserted
  - For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel
- Logical channel transfer composition

  A DMA transfer is divided automatically into a number of transactions. Depending on the logical channel context configured, the transfer size, start address alignment, addressing mode, and

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

configured maximum burst size, each transaction can be a single access or a burst of accesses.

- Logical channel scheduling

  When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

  In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bits (WRITE_PRIORITY and READ_ PRIORITY) in the logical channel DMA4_CCRi register determine whether a logical channel is queued as high or low priority. A software-configurable 8-bit priority counter gives weighting to the priority write queue. For every N (1 to 255) schedules from the priority write queue, one is scheduled from the regular write queue. A channel that is scheduled goes to the end of the queue after it completes its turn on the port. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register using the DMA4_GCR[23:16] ARBITRATION_RATE bit field.

  NOTE: The DMA4_GCR[23:16] ARBITRATION_RATE bit field does not depend on the DMA4_GCR[13:12] HI_THREAD_RESERVED bit field. The ARBITRATION_ RATE bit field depends on the DMA4_CCRi[26] WRITE_PRIORITY bit and the DMA4_CCRi[6] READ_PRIORITY bit.

- Read/write port access scheduling policy

  When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue.

  When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during its block transfer.

The DMA_SYSTEM module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting
- At least one free thread ID is available

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

NOTE: If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

When only one channel is enabled, only one thread is allocated for the channel. In such a situation the channel can have maximum of four outstanding commands (without getting the responses) without rescheduling the channel at the end of each transaction. Each command can be either single access (8-bit, 16-bit or 32-bit) or burst access (2 × M, 4 × M, 8 × M or 16 × M, where M can be 8, 16, or 32 bits).

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see Section 16.4.2.1, *Interrupt Generation*).

16.4.4 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the DMA4_GCR[7:0] MAX_CHANNEL_FIFO_DEPTH bit field. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) 1.

16.4.5 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements (EN), and each element can have a size of 8, 16, or 32 bits (ES), as follows:

transfer block size = FN × EN × ES

The FN, EN, and ES are common for the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the ES, even across consecutive frames.
- Single-index: The address increases by the ES plus the element index (EI) value minus 1 (even across consecutive frames).
- Double-index: The address increases by the ES plus the EI value minus 1 within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI must be such that, when added to the logical channel address pointer, it results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

NOTE: The source and destination start addresses must also be aligned on an ES boundary.

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and a misaligned address error interrupt occurs, if enabled (see Section 16.4.2.1, *Interrupt Generation*).

The DMA4_CFNi register configures the FN in a block.

The DMA4_CENi register configures the EN.

The DMA4_CSDPi register configures the ES.

The DMA4_CSSAi and DMA4_CDSAi registers configure the source and destination start addresses.

The DMA4_CCRi register configures the source and destination addressing modes.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The DMA4_CSEIi, DMA4_CSFIi, DMA4_CDEIi, and DMA4_CDFIi registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n + 1) = A(n)$$

NOTE: Constant addressing mode with DMA4 to/from DDR memory is not supported on the device. To fill the DDR memory with a single value, the constant fill feature of the DMA4 must be used, instead of a constant-addressing mode transfer.

Equation 2. Post-increment addressing:

$$A(n + 1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n + 1) = A(n) + ES + (EI\ 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter ≠ 0):

$$A(n + 1) = A(n) + ES + (EI\ 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter ≠ 0):

$$A(n + 1) = A(n) + ES + (FI\ 1)$$

Calculate the element and frame index as follows:

Equation 5. EIement index

$$EI = [(Stride\ EI\ 1) * ES] + 1$$

Equation 6. Frame index

$$FI = [(Stride\ FI\ 1) * ES] + 1$$

where:

A(n): Byte address of the element *n* within the transfer.

ES is in bytes, ES{1, 2, 4}.

EI is in bytes, specified in a configuration register, 32768 EI 32767.

Stride EI: The difference in the number of elements between the start of the current element *n* to the start of next element, *n+1*.

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, DMA4_CENi.

FI is in bytes, specified in a configuration register, 2147483648 FI 2147483647.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, DMA4_CFNi.

Figure 16-6 shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is used in the 90-degree clockwise image rotation example shown in Figure 16-10.) The double-index addressing example shown in Figure 16-6 uses ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

Figure 16-6 through Figure 16-9 show examples of addressing mode configurations. Table 16-9 lists parameter values for the examples.

Figure 16-9. Addressing Mode Example (c)

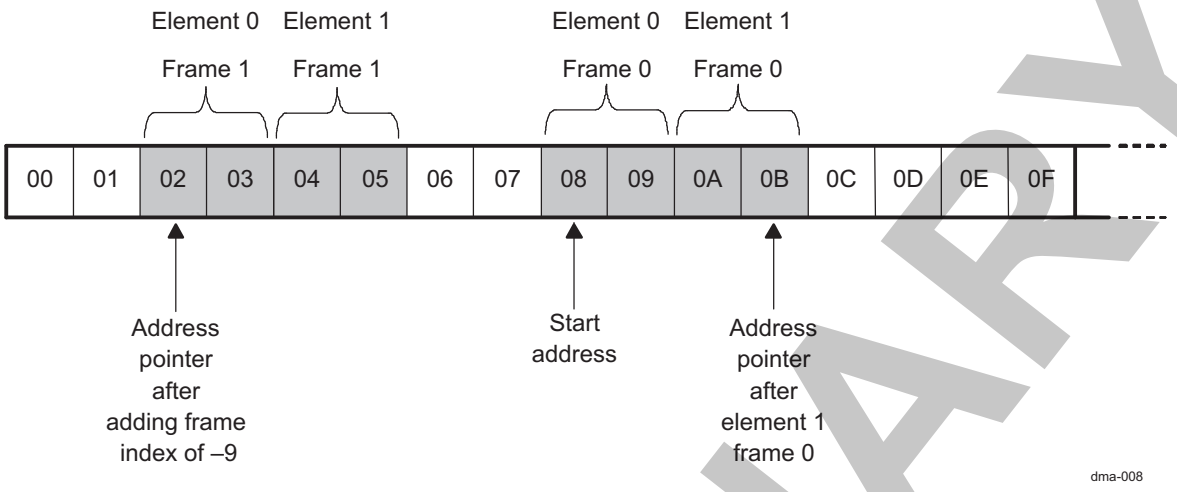

Table 16-9. Parameter Values for Addressing Mode Examples (a), (b), and (c)

Parameter	Example (a)	Example (b)	Example (c)
Addressing mode	Single index (or post-increment)	Double index	Double index
Start address	0	0	8
ES	4 (32-bit)	4 (32-bit)	2 (16-bit)
EN	3	2	2
EI	1	5	1
FN	1	2	2
Frame index	N/A	5	-9

Double indexing can occur on source (read) or destination (write). Equations for rotation of xx degrees on destination are obtained by taking equations for rotation of (360 – xx) degrees on source, and swapping the width (x) and height (y) of the image in them. The opposite is also true. Table 16-10 lists the equations for 90-, 180-, and 270-degree rotations.

Table 16-10. Equations for Rotation

		90° Rotation	180° Rotation	270° Rotation
Double indexing on destination (write)	Base address	ES*(y–1)	ES*(x*y–1)	ES*y*(x–1)
	EI	ES*(y–1) + 1	1–2*ES	1–ES*(y + 1)
	FI	1 ES*[(x–1)*y + 2]	1–2*ES	1+ES*(x–1)*y
Double indexing on source (read)	Base address	ES*x*(y–1)	ES*(x*y–1)	ES*(x–1)
	EI	1–ES*(x + 1)	1–2*ES	ES*(x–1) + 1
	FI	1+ES*(y–1)*x	1–2*ES	1 ES*[(y–1)*x + 2]

Table 16-11 and Figure 16-10 show the configuration required to perform a 90-degree clockwise rotation of a 240 × 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line-by-line starting at the left end of the top line.

NOTE: The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination, FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

Rotations:

Section 16.5.7, *90-Degree Clockwise Image Rotation*, describes how to program an example of a 90-degree clockwise image rotation.

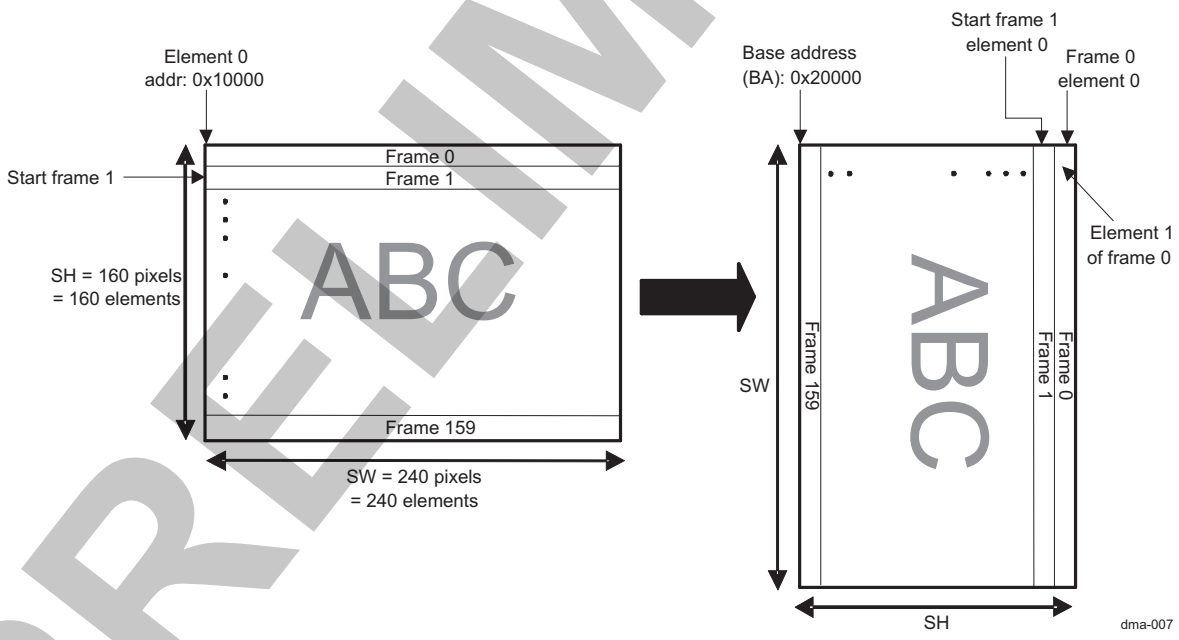
Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

Table 16-11. Example Parameter Values for a 90-Degree Clockwise Image Rotation

Parameter	Source Value	Destination Value
Bits per pixel	32	32
ES	4	4
Image width	SW	SH
Image height	SH	SW
Stride elements (stride EI)	1 element	SH
Stride frames (stride FI)	1 element	–[(SW-1)*SH + 1] = 38,241 elements
Start address	0x100000	0x200000 + (SH 1) x ES = 0x20027C
EN	SW	SW
EI	[(Stride EI 1) * ES] + 1 = 1	[(Stride EI 1) * ES] + 1 = 637
FN	SH	SH
FI	[(Stride FI 1) * ES] + 1= 1	[(Stride FI 1) * ES] + 1 = 152,967

Figure 16-10. Example of a 90-Degree Clockwise Image Rotation



16.4.6 Packed Accesses

To pack data means to group data to match the bus size, thus optimizing a transfer. When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (post-increment mode or single- or double-index mode with EI = 1), the number of elements to transfer in each read/write port access can be maximized by specifying that the source or destination is packed through the channel DMA4_CSDPi register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (four elements per access) and 16 bits (two elements per access).

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access can be only partially filled. This is indicated to the source or destination using the byte-enable signals.

16.4.7 Burst Transactions

Transfer performance can be improved so that the source or destination and addressing profile supports it. This can be achieved by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equal to 16, 32, or 64 bytes through the DMA4_CSDPi register, with the read burst size programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses must be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

NOTE: If post-incrementing is used, data must be packed to DMA data-port width, to use burst.

16.4.8 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the DMA4_CSDPi register for the particular logical channel. If the endianism of the source and destination differ, and if the logical channel ES is less than the DMA_SYSTEM module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that equals the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to instruct the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel DMA4_CSDPi register.

NOTE: Because the device is little-endian by construction, the DMA_SYSTEM endianism registers must never be set to big-endian.

If DMA_SYSTEM is used to execute endian conversion by setting the source and destination to different endianism values, it is important to consider that the L3_MAIN interconnect also executes endian conversion if the DMA_SYSTEM and the source or destination have a different data bus width.

16.4.9 Transfer Synchronization

A logical channel can be programmed for software-triggered or hardware synchronized transfers.

16.4.9.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA DMA4_CCRi[4:0] and DMA4_CCRi[20:19] bit fields to 0. The transfer starts as soon as the DMA DMA4_CCRi[7] bit is set (when it enters the scheduling process).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

16.4.9.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from the source or destination target. A hardware-synchronized transfer is specified by configuring the DMA request line number in the channel DMA4_CCRi register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see Table 16-8).

Specify the DMA request number in the DMA4_CCRi[4:0] SYNCHRO_CONTROL and DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER bit fields. After the DMA4_CCRi[7] ENABLE bit is set, the logical channel becomes enabled but not activated (it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

NOTE: The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, the DMA4_CCRi[4:0] SYNCHRO_CONTROL bit field must be set to 0x2 (DMA request number + 1).

NOTE: A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared among several chained logical channels.

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel DMA4_CCRi register and the DMA4_CCRi[5] FS and DMA4_CCRi[18] BS bits, respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by data type. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independently of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify the packet size.

To support the burst mode, the logical channel must also be configured in target-port packed access mode.

The packet size is configured based on the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit through either the channel DMA4_CDFIi register (source synchronized) or the DMA4_CSFIi register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

Block_size = Number_of_Frame_in_Block * Number_of_Element_in_Frame * Element_Size

- Synchronized at the source

  The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see Section 16.4.13, *Reprogramming an Active Channel*).

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

For a source synchronized transfer, buffering can be enabled or disabled by setting the DMA4_CCRi[25] BUFFERING_DISABLE bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary, the DMA module waits for the next DMA request(s) to read enough data to issue an atomic packed/burst write transaction (assuming that the address is packed/burst aligned).

NOTE: Buffering is not performed between frames, even if it is enabled. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the frame transfer size.

- Synchronized at the destination

  The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel DMA4_CCRi[23] PREFETCH bit. Data is prefetched on the read port side before the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see Section 16.4.4, *FIFO Queue Memory Pool*).

  Buffering disable is not allowed for a destination-synchronized transfer.

NOTE: Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Regardless of whether buffering is enabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the DMA4_CSDPi[17:16] WRITE_MODE bit field = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if the buffering disable is on (even if the write mode is specified as WLNP).

Regardless of whether buffering is enabled, the packet interrupt is not generated in the packet source synchronized mode.

CAUTION

The DMA4_CCRi[25] BUFFERING_DISABLE bit must be filled with an allowed value, as specified in Table 16-12.

Table 16-12. Buffering Disable

	BUFFERING_DISABLE (0: Buffering enable, 1: Buffering disable)	
Destination synchronized	0	Allowed
	1	Not allowed
Source synchronized	0	Allowed
	1	Allowed

- Synchronized transfer monitoring using CDAC (DMA4_CDACi):

  Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.

  The CDAC register is writable; thus, the CDAC can be initialized to monitor the transfer and determine whether the transfer is started (for more information, see Section 16.5.4, *Synchronized Transfer Monitoring Using CDAC*).

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

NOTE: For 16-bit transactions, start reading from or writing to the LSByte first to enable the register update. This is not an issue for 32-bit read-write transactions.

16.4.10 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the number of concurrent channels is greater than the number of available threads.

NOTE: Four threads are available on the read port, and two threads are available on the write port.

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see Section 16.5.5, *Concurrent Software and Hardware Synchronization*):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set in the global register DMA4_GCR[13:12] .

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the DMA4_GCR [13:12] value, the following threadID on the read/write ports are allocated for a high-priority channel:

Read port priority thread reservation:

- DMA4_GCR[13:12] = 0x0 => No ThreadID is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x1 => Read ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x2 => Read ThreadID 0 and Read ThreadID 1 are reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x3 => Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are reserved for high-priority channels.

Write port priority thread reservation:

- DMA4_GCR[13:12] = 0x0 => No ThreadID is reserved for high-priority channels
- DMA4_GCR[13:12] = 0x1 => Write ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x2 => Write ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x3 => Write ThreadID 0 is reserved for high-priority channels.

Regardless of whether the enabled channels are high priority, only the setting of the DMA4_GCR[13:12] value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit (DMA4_CCRi[26]) is added for write priority, and the previous priority bit becomes read priority bit (DMA4_CCRi[6]).

NOTE: The device has one priority bit per logical channel, not one priority bit per port.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

16.4.11 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the DMA4_GCR register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the DMA4_GCR[15:14] HI_LO_FIFO_BUDGET field. The maximum channel FIFO depth is limited by the HI_LO_FIFO_BUDGET field as follows:

If the channel is low priority:

- When HI_LO_FIFO_BUDGET = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When HI_LO_FIFO_BUDGET = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user must perform the following equation:

- For a high-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of High Channel =< High Budget FIFO
- For a low-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of Low Channel =< Low Budget FIFO

NOTE: Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

16.4.12 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel DMA4_CLNK_CTRLi register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it may be all, none, or simply the first one). The DMA request line number must be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit. The looping transfer stops after the specified channel transfer is complete.

NOTE: A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

For more information about the programming model, see Section 16.5, *DMA_SYSTEM Basic Programming Model*.

16.4.13 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the DMA4_CCRi[7] ENABLE bit. When an ongoing transaction is complete and the read-active and write-active bits in the DMA4_CCRi register (DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

16.4.14 Packet Synchronization

A packet transfer notion is related to the behavior of some peripherals, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:

maximum_transfer_size =peripheral_FIFO_depth x number_of_frame_in_block

The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on a read port or a write port if source target or destination target is packet synchronized respectively.

Example:

Consider a camera interface with a FIFO_depth of 128 words and a FIFO_element_number_threshold of 128, and a picture to transfer with a size 320 lines by 240 columns. If frame synchronization is associated with each DMA request then the maximum transfer size that can be performed is $128x2^{16}$ words. In this case, a frame is 128-word long, which does not fit the size of a line, and it is not possible to generate an interrupt at the end of line. However, by introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size (maximum_transfer_size = 2^{24} x 2^{16} words) is independent of both peripheral_FIFO_depth and FIFO_element_number_threshold. This allows a long-enough transfer within one channel context and rotation operation on a large image format.

The main features of DMA Packet transfer are as follows:

- DMA Packet_Data_Size for each DMA Request: The Peripheral_element_number_threshold (the number of elements in a packet) shares the DMA4_CSFIi and DMA4_CDFIi configuration registers. If the peripheral is the source target, the addressing mode is constant, and the DMA4_CSFIi[15:0] bit field is used to specify the packet data size in the DMA4_CSFIi register. The user must set the DMA.SDMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 1. If the peripheral is the destination target, the addressing mode is constant, the DMA4_CDFIi[15:0], is used to specify the packet data size (PKT_ELNT_NBR), and the bit field [31:16] is unused. To specify the packet data size in the DMA4_CDFIi register, the user must set the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 0.

  NOTE: The packet size can be a submultiple or non-submultiple of a frame size. If DMA Packet_Data_Size is aligned on the DMA channel block data size boundary, then DMA transfers the last data in the channel block boundary and stops at the block boundary for the last packet DMA Request. If the Packet_Data_size is not aligned on the block boundary, the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block.

- DMA Packet_Data_Transfer does not affect DMA channel capabilities in term of packing and bursting.

  The packet synchronization mode is active when DMA4_CCRi[5] FS = DMA4_CCRi[18] BS = 1. Then:

  – If DMA4_CCRi[24] SEL_SRC_DST_SYNC = 0, the DMA4_CDFIi[15:0] bit field gives the number of elements in the packet and the DMA4_CDFIi[31:16] bit field is unused for the packet size.

  – If DMA4_CCRi[24] SEL_SRC_DST_SYNC = 1, the DMA4_CSFIi[15:0] bit field gives the number of element in the packet and the DMA4_CSFIi[31:16] bit field is unused for the packet size.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: The maximum transfer size, regardless of the packet size, is always:

Block_size = Number_of_Frame_in_Block x Number_of_Element_in_Frame x Element_Size.

If DMA channel packet/burst access is across the packet boundary, the DMA hardware automatically splits this packing/burst access into multiple smaller accesses that are aligned on the packet boundary. Otherwise, the DMA transfers data as a usual packing/burst access.

16.4.15 Graphics Acceleration Support

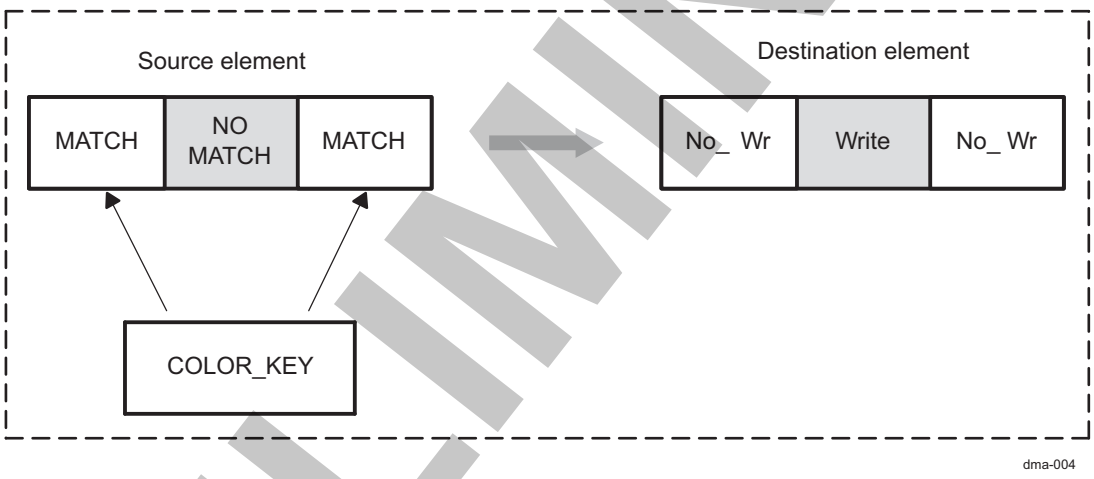
The DMA_SYSTEM supports two graphic acceleration features: transparent copy and constant fill.

Only one of these features can be enabled at a time through the DMA4_CCRi register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the DMA4_COLORi register so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination but instead leaves the data in the corresponding location in the destination as it is.

Figure 16-11 shows the 2-D graphic transparent color block diagram.

Figure 16-11. 2-D Graphic Transparent Color Block Diagram



The constant fill feature provides the ability to specify a particular color through the DMA4_COLORi register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8, 16, and 24 bpp, depending on what is specified as the DMA transfer ES through the DMA4_CSDPi register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the 8 most-significant bits (MSBs) ([31:24]) are 0. Both features are compatible with packed and burst transactions.

16.4.16 Supervisor Modes

A logical DMA channel can be configured to operate in supervisor mode through the DMA4_CCRi[22] SUPERVISOR bit. This must be done using supervisor access. Once a channel is configured in supervisor mode, the channel configuration is protected from nonsupervisor accesses. All DMA transactions on a supervisor channel are supervisor transactions.

16.4.17 Posted and Nonposted Writes

A logical channel can be configured in its DMA4_CSDPi[17:16] bits to use one of three write access handshake modes for the destination:

- Nonposted write: Each write must complete before transfer can continue or complete.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

- Posted write: Transfer continues without waiting for each write to complete (may improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write completes before transfer can complete.

16.4.18 Disabling a Channel During Transfer

When a channel is disabled during a transfer, the channel undergoes an abort, unless it is hardware-source-synchronized with buffering enabled (DMA4_CCRi[25] BUFFERING_DISABLE = 0). If this is the case, the FIFO is drained to prevent the loss of data. For more information about this feature, see Section 16.4.19, *FIFO Draining Mechanism*.

16.4.19 FIFO Draining Mechanism

When a source-synchronized channel is disabled during a transfer, the current hardware request (element/packet/frame/block) service completes and the channel DMA4_CCRi[9] RD_ACTIVE bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the DMA4_CCRi[10] WR_ACTIVE bit is set to 0 (channel is no longer active on the write port) and if the DMA4_CICRi[12] DRAIN_END_IE is set to 1, the DMA4_CSRi[12] DRAIN_END status bit is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it must wait for the DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE bits to become 0 before being reenabled for a new transfer. The FIFO drain for a channel occurs only in the following cases:

- If the channel is a source synchronized channel and DMA4_CCRi[25] BUFFERING_DISABLE = 0 and
- If the channel is not a solid fill channel and
- If the channel is not a transparent and copy channel and
- If the channel is a hardware, synchronized channel

NOTE: For a self-linked or chain-linked channel, the user must disable the DMA4_CLNK_CTRLi[15] ENABLE_LINK bit before disabling the channel.

In all other cases, the channel undergoes an abort.

16.4.20 Linked List

16.4.20.1 Overview

The DMA_SYSTEM supports the logical transfer-descriptor loader feature. A transfer descriptor represents a set of values that maps to a set of logical channel configuration registers.

A logical channel transfer descriptor can be loaded by DMA from memories, and then successive transfer descriptors can be autonomously loaded based on a linked-list scheme. This enables DMA4 scatter-gather transfers with minimum MPU support by removing successive channel configuration processing and associated interrupt handling overheads. It also optimizes DMA4 channel resources by enabling efficient transfer serialization on a single logical channel versus concurrent (multiple) logical channel use.

Different types of transfer descriptors are supported (full or partial logical channel configuration registers are set). This optimizes the memory size required for storing a long linked list, because parameter changes are limited to only a few logical channel configuration registers.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

16.4.20.2 Link-List Transfer Profile

A linked-list transfer can be seen as a super-block transfer (where the block is composed of FN frames and each frame includes EN elements). The block size (FN x EN x ES) can be changed in the linked list by loading an updated transfer descriptor.

The end of the super block is signaled in the last descriptor associated with the last block. Generally, for a given link-list transfer, the logical channel is set at the beginning of the transfer and the logical channel configurations for the subsequent blocks are slightly changed. Thus, the descriptor can be limited to an update of only few parameters, such as FN or EN. This assumes that the content of unmodified registers is preserved when a new descriptor is loaded.

A transfer descriptor is composed of a set of channel configuration register values with the addition of the next-descriptor pointer register (DMA4_CNDPi) and a channel-descriptor parameter register (DMA4_CDPi) . The next-descriptor pointer is the 32-bit address pointer from where the next transfer descriptor is to be loaded. The next-descriptor pointer is mapped depending on the descriptor type (1, 2, or 3).

16.4.20.3 Descriptors

A transfer descriptor is a set of values that maps to a set of logical channel configuration registers. The descriptor contains the parameters associated with a transfer profile (transfer size, source or destination addresses, etc). Four different types of transfer descriptors are supported to optimize the memory size required to store a long linked list and to minimize MPU use to create and maintain the descriptor list.

A transfer descriptor is a list of 32-bit values. A descriptor must be 32-bit aligned in memory. Only the 30 least-significant bits (LSBs) of the next-descriptor address pointer are updated from the descriptor, and the DMA4 forces the 2 LSBs to 0 on generation of the pointer address. The descriptor size is variable, depending on the descriptor type and the Nxt_Dv and Nxt_Sv bit fields.

Transfer descriptor bit mapping is the same as DMA4 logical-channel configuration register bit mapping, with the following exceptions:

- Src_Element_index and Dst_Element_index are concatenated in the same 32-bit location.
- DMA4_CICRi (interrupt event mask)
- CFN (frame number)
- Bit fields:
  - P: Corresponds to the PAUSE_LINK_LIST bit:
    - When set to 1 in the descriptor, the channel is suspended when the descriptor load completes.
    - The user must not set the PAUSE_LINK_LIST bit through the configuration port. Otherwise, behavior is undefined.
    - When set to 0 (through the configuration port) after pause, the linked-list channel resumes its transfer (descriptor load or data load).
  - B: Corresponds to the end-of-block enable bit (BLOCK_IE) of the DMA4_CICRi register; valid only for type 3. This value is don't care for descriptor types 1 and 2, where DMA4_CICRi is fully specified.
  - Nxt_Dv, Nxt_Sv: Mapped in the DMA4_CDPi register. They indicate one of the following possibilities:
    - Next descriptor contains an updated destination or source address.
    - Next descriptor does not update the source or destination address, but increments the last source or destination address (from the end of the last transfer).
    - The next source address and/or destination address are the last valid ones in the configuration memory. This means that the corresponding location in the configuration memory is not updated (assuming that they were initialized at least once in the past). This is also called wrapping addressing.
  - Next_Descriptor_Type: Specifies the next descriptor type that corresponds to the NEXT_DESCRIPTOR_TYPE bit field in the DMA4_CDPi register

PRELIMINARY

16.4.20.3.1 Type 1

A type 1 descriptor includes the overall channel configuration register value to be loaded (global registers are not part of the type 1 descriptor). This descriptor is used primarily when major changes are required:

- Channel read or write access profiles must be modified; for example, bursting and packing (included in the DMA4_CSDPi register)
- Attach a new DMA request to the same channel or change the priority or access privilege (included in the DMA4_CCRi register)
- Enable solid or transparent color fill (included in the DMA4_CCRi and DMA4_COLORi registers)
- Enable a channel link (included in the DMA4_CLNK_CTRLi register)

Table 16-13 shows a type 1 descriptor.

Table 16-13. Type 1

16.4.20.3.2 Type 2

A type 2 descriptor includes the overall logical channel transfer address register and transfer format register to be loaded. This descriptor enables 2D addressing linked-list transfer (for example, a multimedia application where 2D objects are moved in a link). Table 16-14 shows a type 2 descriptor with source and destination address updates. Table 16-15 shows a type 2 descriptor with one source or destination address update.

16.4.20.3.3 Type 3

A type 3 descriptor is limited to a few logical channel transfer address registers and transfer format registers to be loaded. This descriptor enables simple 1D addressing link transfer (for example, scatter-gather or ping-pong memory movement using a linked list). Table 16-16 shows a type 3 descriptor with source and destination address updates. Table 16-17 shows a type 3 descriptor with one source or address destination update.

16.4.20.4 Linked-List Control and Monitoring

16.4.20.4.1 Transfer Mode Setting

Four descriptor types are available in DMA4_CDPi[9:8] TRANSFER_MODE to distinguish the different transfer modes:

- DMA4_CDPi[9:8] TRANSFER_MODE = 00: The current channel is using normal mode.
- DMA4_CDPi[9:8] TRANSFER_MODE = 01: The current channel is using link-list channel mode for a type 1, 2, or 3 descriptor.

The reset value is normal mode (DMA4_CDPi[9:8] TRANSFER_MODE = 0).

16.4.20.4.2 Starting a Linked List

Like a nonlinked-list transfer, a link transfer starts under host control by enabling the associated logical channel (set the DMA4_CCRi[7] ENABLE bit to 1). The DMA4_CDPi[10] FAST bit sets the start mode of the link-list transfer:

In nonfast-start mode, the logical channel configuration is fully initialized so that the transfer can start without descriptor loading.

In fast-start mode, the descriptor pointer and other inputs are given. The channel starts by loading the descriptor and then starts the data transfer phase.

16.4.20.4.3 Monitoring a Linked-List Progression

In addition to the DMA4_CCENi (remaining elements) and DMA4_CCFNi (remaining frames) registers that are used to monitor the transfer progress, a per-channel register, DMA4_CCDNi (channel current active descriptor number), monitors which descriptor in the list is active. The user must initialize the DMA4_CCDNi register to 0 during the initial configuration. When the DMA4_CCDNi register is updated, the DMA4_CCFNi and the DMA4_CCENi registers are updated. The user must also initialize the DMA4_CCFNi and DMA4_CCENi registers to 0xFFFF and to 0xFFFFFF, respectively, to track the effective transfer start of synchronized transfer.

16.4.20.4.4 Interrupt During Linked-List Execution

Any logical channel source of interrupt can be triggered during a linked-list execution, if the interrupt source is enabled during the initial configuration in CICR. The DMA4_CICRi register can also be updated during the linked-list execution if descriptor types 1 and 2 are used.

The use of an interrupt event in a link execution can be difficult, because the link can progress in parallel with interrupt service routine (ISR) execution. This makes it difficult to synchronize them unless system assumptions are used. The most appropriate synchronization model is to get an interrupt-only on linked-list completion, when the last transfer block is complete. This prevents the interrupt from occurring during the link execution. An end-of-super-block interrupt event available in the DMA4_CICRi and DMA4_CSRi registers can be enabled at initial configuration or when using descriptor types 1 and 2. To prevent the use of descriptor type 1 or 2 to update BLOCK_IE (full DMA4_CICRi update), a dedicated BLOCK_IE bit field is also available in a type 3 descriptor.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

16.4.20.4.5 Pause a Linked List

When the channel is suspended, it remains enabled.

The pause behaves differently, depending on the transfer mode:

- Normal transfer mode: If the user sets the DMA4_CDPi[7] PAUSE_LINK_LIST bit to 1, the channel completes the current read and write transactions and then suspends the channel. The channel can be resumed by setting the channel DMA4_CDPi[7] PAUSE_LINK_LIST bit to 0.
- Linked-list type 1, 2, or 3 mode: The user must not set the DMA4_CDPi[7] PAUSE_LINK_LIST bit through the configuration port; otherwise, transfer behavior is undefined.

  A PAUSE_LINK_LIST bit (P) is set to 1 in the descriptor.

  – The channel is suspended after the descriptor load, translation, and configuration memory update are complete.
  – The linked list can be resumed by resetting the DMA4_CDPi[7] PAUSE_LINK_LIST bit (through the configuration port).

16.4.20.4.6 Stop a Linked List (Abort or Drain)

The channel can be stopped for a drain or an abort. These cases are exclusive.

16.4.20.4.6.1 Drain

- Drain conditions:

  A channel is a drain candidate if it is a hardware-source-synchronized transfer with DMA4_CCRi[25] BUFFERING_DISABLE = 0 and should not be doing any of the graphics operation (transparent copy or solid-color fill).
- Drain trigger:

  A drain candidate channel is drained if it is disabled (DMA4_CCRi[7] ENABLE = 0) or if it receives a transaction error on the read port.
- Drain behavior with a type 1, 2, or 3 descriptor. Drain trigger can occur in two situations:
  – During descriptor loading: Any ongoing current transaction is complete and the channel is aborted.
  – During data loading: The read is completed at the boundary of the request (element/frame/packet/block boundary), the FIFO is drained to the destination, and then a DRAIN_END interrupt can be asserted.

16.4.20.4.6.2 Abort

- Abort condition:

  A channel is an abort candidate if it is software-synchronized, hardware-destination-synchronized, solid color-fill, transparent-color fill, or hardware-source-synchronized with DMA4_CCRi[25] BUFFERING_DISABLE = 1.
- Abort trigger:

  A channel is an abort candidate if it is disabled (DMA4_CCRi[7] ENABLE = 0), if it receives a transaction error on the read or write port, or if there is a MISALIGNMENT_ERROR.
- Abort behavior with a type 1, 2, or 3 descriptor:

  If an abort trigger occurs, the channel aborts immediately after completion of current read/write transactions and then the FIFO is cleaned up.

  In type 1, 2, or 3, if an abort trigger or drain trigger occurs during the descriptor load phase, the channel aborts.

16.4.20.4.7 Status Bit Behavior

This section describes the behavior of the DMA4_CSRi[6] SYNC, DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE status bits:

- For a hardware-synchronized channel in linked-list mode, the DMA4_CSRi[6] SYNC bit becomes active (DMA4_CSRi[6] SYNC = 1) when the first data load transaction is scheduled and remains active

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

until the last data load transaction in the block (not super block) is descheduled (DMA4_CSRi[6] SYNC = 0). The SYNC bit is not active during the descriptor load phase.

- The DMA4_CCRi[9] RD_ACTIVE bit is active during the data load phase and the descriptor load phase. It becomes active when the first read transaction is scheduled. It becomes inactive:
  - When (during the descriptor load phase) the last descriptor write request is descheduled
  - When (during the data load phase) the last read transaction in the block (not super block) is descheduled for software-synchronized transfer or destination-synchronized transfer with prefetch enabled
  - When (during the data load phase) the last read transaction in the request (element/frame/packet/block sync) is descheduled for hardware-source-synchronized transfer or hardware-destination-synchronized transfer without prefetch
- The DMA4_CCRi[10] WR_ACTIVE bit is active only during the data load phase. It becomes active when the first write transaction is scheduled and becomes inactive:
  - Until the last write transaction in the block (not super block) is descheduled and the FIFO is cleaned up for software-synchronized transfer
  - Until the last write transaction in the request (element/frame/packet/block sync) is descheduled and the FIFO is cleaned up for hardware-source-synchronized transfer (with DMA4_CCRi[25] BUFFERING_DISABLE = 0) or hardware-destination-synchronized transfer.

16.4.20.4.8 Linked-List Channel Linking

Channel linking for inter- and intra-super blocks is supported for type 1, 2, and 3 descriptors.

Assume that CHx and CHz are linked-list channels using generic descriptors. If CHx is composed of N descriptors and CHz is composed of M descriptors, then in nonfast mode:

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]->CHx[DataN + 1]

CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM + 1]

It is possible to link CHx to CHz or CHx to itself after the completion of the CHx transfer (end of super block). To do this, the user must set the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit to 1 and the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit to z (or to x for self linking) through the last descriptor using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]-CHx[DataN+1] -> CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM+1]

It is also possible to link CHx to CHz during the CHx transfer and before the end of super block. The user must set the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit to 1 and the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit to z through descriptor p (CHx[DESp]) using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] ->.-> CHx[DESp]->CHx[Data(p + 1)] -> CHz[Data1]-> CHz[DES1] -> .

The user must continue the linking until channels CHx and CHz complete their super-block transfers; otherwise, the channels remain enabled.

NOTE: In channel linking, the head of a chain can be in fast mode or nonfast mode. All channels that are not in the head of the chain can be in nonfast mode only. In self-linking, the channel cannot be in fast mode.

NOTE: If channel CHx links to CHz in the middle of the superblock transfer (remember link bit can be set through Type-1 descriptor load), CHx is disabled after the corresponding data load and enables the channel CHz.

16.5 DMA_SYSTEM Basic Programming Model

16.5.1 Setup Configuration

After a hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the DMA4_GCR register, and any required interrupts must be enabled through the DMA4_IRQENABLE_Lj registers and the logical channel DMA4_CICRi registers.

Software clears the DMA4_CSRi register and the IRQSTATUS bit for the different interrupt lines before enabling the channel.

16.5.2 Software-Triggered (Nonsynchronized) Transfer

To program a software-triggered DMA transfer:

1. Configure the transfer parameters in the logical DMA channel registers:
   - DMA4_CSDPi:
     - Transfer ES (8, 16, or 32 bits) in the DMA DMA4_CSDPi[1:0] bit field.
     - Read and write port access types (single/burst), DMA DMA4_CSDPi[8:7] and DMA4_CSDPi[15:14] bit fields
     - Source and destination endianism, DMA DMA4_CSDPi[21] and DMA4_CSDPi[19] bits
     - Write mode (posted or nonposted) and DMA DMA4_CSDPi[17:16] bit field
     - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA DMA4_CSDPi[6] and DMA4_CSDPi[13] bits
   - DMA4_CENi: EN
   - DMA4_CFNi: FN per transfer block
   - DMA4_CSSAi and DMA4_CDSAi: Source and destination start address (aligned with transfer ES)
   - DMA4_CCRi:
     - Read and write port addressing modes, DMA DMA4_CCRi[13:12] and DMA4_CCRi[15:14] bit field
     - Priority bit for both read and write ports, DMA DMA4_CCRi[6] and DMA4_CCRi[26] bits
     - DMA request number (set to 0 for a software-triggered transfer) and DMA register bit fields DMA4_CCRi[4:0] = 0 and DMA4_CCRi[20:19] = 0
   - DMA4_CSEIi, DMA4_CSFIi, DMA4_CDEIi, and DMA4_CDFIi: Source and destination element and frame indexes (depending on addressing mode)
2. Start the transfer through the enable bit in the channel DMA4_CCRi register and DMA DMA4_CCRi[7] bit

The following example performs a DMA transfer on channel 10 of a 240*160 picture from RAM to RAM (0x80C00000 to 0x80F00000):

```
UWORD32 RegVal = 0;
DMA4_t *DMA4;
DMA4 = (DMA4_t
      *)malloc(sizeof(DMA4_t));

/* Init. parameters
      */
DMA4->DataType = 0x2; //
      DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0; //
      DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0; //
      DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; //
      DMA4_CSDPi[21]
```

```

16.5.3 Hardware-Synchronized Transfer

To monitor a hardware synchronized DMA transfer, initialize the DMA4_CDACi register before the software enable.

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization DMA4_CCRi[5] FS bit and the block synchronization DMA4_CCRi[18] BS bit must be programmed. For all the following synchronized transfers (element, packet, and frame or block-synchronized transfers), the user must first set the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 1 when the source triggers on the DMA request and set it the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 0 when the destination triggers on the DMA request.

NOTE: The user must take care when setting the DMA4_CCRi[23] PREFETCH bit it is in conjunction with DMA4_CCRi[24] SEL_SRC_DST_SYNC bit.

- To configure an LCh to transfer one element per DMA request:
  1. Set the number of DMA request associated with the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  4. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
  5. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
  6. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
  7. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
  8. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
  9. Set both FS and BS to 0 in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
  10. Set to 1 the channel enable bit DMA4_CCRi[7] EN.
- To configure an LCh to transfer one frame per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of element per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  4. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

bit field.

5. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
6. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
7. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
8. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
9. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
10. Set FS to 1 and BS to 0, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
11. Set to 1 the channel enable bit DMA4_CCRi[7] EN.

- To configure an LCh to transfer one block per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of element per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  4. Set in the DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH gets disabled.
  5. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  6. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
  7. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
  8. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
  9. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
  10. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
  11. Set FS to 0 and BS to 1, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
  12. Set to 1 the channel enable bit DMA4_CCRi[7] EN.
- To configure an LCh to transfer one packet per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of elements per packet to transfer: If the packet requestor is in the source, set DMA4_CCRi [24] SEL_SRC_DST_SYNC to 1 and set the packet element number in the DMA4_CSFIi register and set the addressing mode of source to constant addressing in DMA4_CCRi[13:12] SRC_AMODE bit field; else, if the packet requestor is in the destination, set the DMA4_CCRi[24] SEL_SRC_DST_SYNC to 0 and set the packet element number in the DMA4_CDFIi register and set the addressing mode of destination to constant addressing in DMA4_CCRi[15:14] DST_AMODE bit field.
  4. Set the number of elements per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  5. Set in the DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frames (transfers), to take place before the LCH gets disabled.
  6. Set the element number in the packet in the DMA4_CSFIi[15:0] PKT_ELNT_NBR, if constant addressing or post-incremented addressing modes are used in the source side. However, the number of element in the packet is set in the DMA4_CDFIi[15:0] PKT_ELNT_NBR if constant addressing mode is used in the destination side.
  7. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  8. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

9. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
10. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
11. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
12. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
13. Set FS to 1 and BS to 1, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
14. Set to 1 the channel enable bit DMA4_CCRi[7] EN.

NOTE: It is possible to stop a transfer by disabling the channel by resetting the DMA4_CCRi[7] ENABLE bit.

16.5.4 Synchronized Transfer Monitoring Using CDAC

The DMA4_CDACi register is writable and non-initialized (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in the DMA4_CDACi register.
2. Enable the channel.
3. If a time-out occurs, read DMA4_CDACi register.
4. If DMA4_CDACi != 0 (it is the value configured in DMA4_CDACi):

   This indicates that the corresponding transfer has started. The user can then rely on DMA4_CCENi and DMA4_CCFNi element and frame counters.

   Otherwise, if DMA4_CDACi = 0 (it is the value configured in the DMA4_CDACi):

   This indicates that the corresponding transfer did not start.

16.5.5 Concurrent Software and Hardware Synchronization

This section describes thread allocation only; it does not describe the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread at least on the synchronized target side.

Even for multiple concurrent channels, thread reservation ensures that when a hardware DMA request arrives, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider six concurrent channels:

- Channels 0, 1, 2, and 3 are dedicated to memory-memory transfer; they are software triggered and not synchronized.
- Channel 4 is dedicated to memory-peripheral transfer, hardware triggered, and synchronized on the write side.
- Channel 5 is dedicated to peripheral-memory transfer, hardware triggered, and synchronized on the read side.

To perform thread reservation:

1. Allow thread reservation for priority channel 4 and channel 5:

   Reserve one thread (Read ThreadID 0) on the read port and one thread (Write ThreadID 0) on the write port: set the DMA4_GCR[13:12] HI_THREAD_RESERVED bit field to 0x1.
2. Specify channel priority:

   Channel 4 is a write high priority channel: set DMA4_CCRi[26] WRITE_PRIORITY = 1.

   Channel 5 is a read high priority channel: set DMA4_CCRi[6] READ_PRIORITY = 1.

16.5.6 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or non-synchronized transfers describe in Section 16.5.5, *Concurrent Software and*

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

Hardware Synchronization.

2. For each channel in the chain, configure the DMA4_CLNK_CTRLi register as follows:
   - Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit field.
   - Include the logical channel to the chain and enable link by setting the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit.
   - For a non-looping chain, the last logical channel in the chain must have the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit set to 0 to indicate the end of the chain.
3. Enable the transfer through the enable bit in the first logical channel DMA4_CCRi[7] ENABLE bit. All other channels in the chain must be disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A non-synchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit (by setting it to 0x0), of the final channel transfer.

In the RAM-to-RAM copy example, to copy in loop, it is possible to link channel 10 on itself. The following line can be added in the channel configuration:

```
/* g) Set link for loop */
DMA4_CLINK_CTRL_CH10 =
      0x0000800A;
```

16.5.7 90-Degree Clockwise Image Rotation

The 90-degree clockwise image rotation example described in Section 16.4.5, *Addressing Modes*, can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:
   - DMA4_CSDPi:
     - Transfer ES = 32-bit (32 bpp), DMA4_CSDPi[1:0] DATA_TYPE bit field
     - Read and write port access types = maximum burst size supported by memory device, DMA4_CSDPi[8:7] SRC_BURST_EN and DMA4_CSDPi[15:14] DST_BURST_EN bit fields
     - Source and destination endianism, DMA4_CSDPi[21] SRC_ENDIAN and DMA4_CSDPi[19] DST_ENDIAN bits
     - Write mode = posted with last element nonposted, DMA4_CSDPi[17:16] WRITE_MODE bit field
     - Source and destination packed = Yes (although destination writes do not benefit because EI1), DMA4_CSDPi[6] SRC_PACKED and DMA4_CSDPi[13] DST_PACKED bits
   - DMA4_CENi: EN = 240
   - DMA4_CFNi: FN per transfer block = 160
   - DMA4_CSSAi: Source start address = 0x100000
   - DMA4_CDSAi: destination start address = 0x20013E
   - DMA4_CCRi:
     - Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, DMA4_CCRi[13:12] SRC_AMODE and DMA4_CCRi[15:14] DST_AMODE bit fields
     - Low or high priority, DMA4_CCRi[6] READ_PRIORITY bit
     - DMA request number = 0 (for software-triggered transfer), DMA4_CCRi[4:0] SYNCHRO_CONTROL and DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER bit fields
   - DMA4_CSEIi: Source EI = 1
   - DMA4_CSFIi: Source frame index = 1
   - DMA4_CDEIi: destination EI = 637
   - DMA4_CDFIi: destination frame index = 152967

PRELIMINARY

2. Start the transfer through the enable bit in the channel DMA4_CCRi register.

The following parameters are used to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code used in Section 16.5.2, *Software-Triggered (Nonsynchronized) Transfer*:

```
/* Init. parameters */
DMA4->DataType = 0x2; //
      DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0x3; // DMA4_CSDPi[8:7]

DMA4->WritePortAccessType = 0x3; // DMA4_CSDPi[15:14]

DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]

DMA4->DestinationEndianism = 0; // DMA4_CSDPi[19]

DMA4->WriteMode = 0x2; // DMA4_CSDPi[17:16]
DMA4->SourcePacked
      = 0x1; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0x1; //
      DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi

DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi

DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAi

DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi

DMA4->SourceElementIndex = 1; // DMA4_CSEIi

DMA4->SourceFrameIndex = 1; // DMA4_CSFIi

DMA4->DestinationElementIndex = 637; // DMA4_CDEIi

DMA4->DestinationFrameIndex = -152967; // DMA4_CDFIi

DMA4->ReadPortAccessMode = 0x3; // DMA4_CCRi[13:12]

DMA4->WritePortAccessMode = 0x3; // DMA4_CCRi[15:14]

DMA4->ReadPriority = 0; // DMA4_CCRi[6]
DMA4->WritePriority =
      0; // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; // DMA4_CCRi[4:0]

DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]
```

16.5.8 Graphic Operations

- Transparent copy:
  1. Set the DMA4_CCRi[17] TRANSPARENT_COPY_ENABLE bit to 1
  2. Set the DMA4_CCRi[16] CONST_FILL_ENABLE bit to 0
  3. Set the value of the key color in the DMA4_COLORi[15:0] COLOR_KEY bit field

  To perform this graphic operation, the following lines can be added to the example of Section 16.5.2, *Software-Triggered (Nonsynchronized) Transfer*.

```
DMA4_CCR_CH10 &= ~(0x1 << 16);
DMA4_CCR_CH10 |= 0x1 << 17;

DMA4_COLOR_CH10 = 0x00000003;
```

- Solid Color fill:
  1. Set the DMA4_CCRi[16] CONST_FILL_ENABLE bit to 1
  2. Set the DMA4_CCRi[17] TRANSPARENT_COPY_ENABLE bit to 0

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

3. Set the value of key the color in the DMA4_COLORi[15:0] SOLID_COLOR bit field

To perform this graphic operation, the following lines can be added to the example of Section 16.5.2, *Software-Triggered (Nonsynchronized) Transfer*.

```
DMA4_CCR_CH10 &= ~(0x1 << 17);
DMA4_CCR_CH10 |= 0x1 << 16;

DMA4_COLOR_CH10 = 0x00000003;
```

16.5.9 Linked-List Programming Guidelines

- With the exception of the DMA4_CCRi[7] ENABLE bit and the DMA4_CDPi[7] PAUSE_LINK_LIST bit during a linked-list transfer (descriptor load phase or data load phase), avoid programming any register through the configuration port.
- Before enabling any linked-list transfer, ensure that all global registers and all registers in the descriptor are initialized. Some static channel registers (registers that are not updated by the descriptor to be loaded) must also be initialized correctly:
  - For type 2, the following registers must be initialized with consistent values:
    - All global registers
    - DMA4_CCRi
    - DMA4_CSDPi
    - DMA4_CLNK_CTRLi
  - For type 3, the following registers must be initialized with consistent values:
    - All global registers
    - DMA4_CCRi
    - DMA4_CSDPi
    - DMA4_CLNK_CTRLi
    - DMA4_CICRi
    - DMA4_CFNi
- In case of a linked list with descriptor types 2 and 3, the content of the DMA4_CCRi register must not change during super-block life.
- The PAUSE_LINK_LIST bit must not be set in the initialization phase.

16.6 DMA_SYSTEM Register Manual

16.6.1 DMA_SYSTEM Instance Summary

Table 16-18. DMA_SYSTEM Instance Summary

Module Name	Base Address	Size
DMA_SYSTEM	0x4A05 6000	4 KiB

16.6.2 DMA_SYSTEM Registers

16.6.2.1 DMA_SYSTEM Register Summary

Index *i* represents the logical channel number (where i = 0 to 31). The offset address for some registers is calculated from the channel *c* number. For example, the DMA4_CCR10 (channel 10) register has an offset address of 10 × 0x60 = 0x3C0, and thus a physical address of 0x4A05 6080 + 0x3C0 = 0x4A05 6440.

Index *j* represents the interrupt line number (where j = 0 to 3) The offset address for some registers is calculated from the channel *c* number. For example, the DMA4_IRQSTATUS_L3 (line 3) register has an offset address of 3 × 0x4 = 0xC, and thus a physical address of 0x4A05 6008 + 0xC = 0x4A05 6014.

16.6.2.2 DMA_SYSTEM Register Description

NOTE: Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

Shadow registers are used to read run-time registers such as CCEN, CCFN, CDAC, and CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive accesses, the value of the previous registers can change. A shadow register holds the entire value to let the next access recover the remaining 24 or 16 bits.

For non-32-bit transactions, start reading or writing from the LSByte first to enable the register update. There is no issue for 32-bit read-write transactions.

15:14	HI_LO_FIFO_BUDGET	Allow to have a separate Global FIFO budget for high and low priority channels. For Hi priority Channel: (Per_channel_Maximum FIFO depth + 1) x Number of active High priority Channel =< High Budget FIFO For Low priority channel: (Per_channel_Maximum FIFO depth + 1) x Number of active Low priority Channel =< Low Budget FIFO 0x0: no fixed budget for neither higher nor lower priority channel 0x1: 75% of FIFO for low priority and 25% for high priority channels 0x2: 25% of FIFO for low priority and 75% for high priority channels 0x3: 50% of FIFO for low priority and 50% for high priority channels	RW	0x0
13:12	HI_THREAD_RESERVED	Allow thread reservation for high priority channel on both read and write ports. 0x0: No ThreadID is reserved on the Read Port for high priority channels. No ThreadID is reserved on the Write Port for high priority channels. 0x1: Read Port ThreadID 0 is reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x2: Read port ThreadID 0 and ThreadID 1 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x3: Read PortThreadID 0, ThreadID 1 and ThreadID 2 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.	RW	0x0
11:8	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
7:0	MAX_CHANNEL_FIFO_DEPTH	Maximum FIFO depth allocated to one logical channel. Maximum FIFO depth can not be 0x0. It should be at least 0x1 or greater. Note that If channel limit is less than destination burst size enough data will not be accumulated in the data FIFO and it will never be sent out on the WR port. The burst size should be less than the FIFO limit specified in this bit field.	RW	0x10

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
29:27	RESERVED	Reserved for non-GP devices	RW	0x0
26	WRITE_PRIORITY	Channel priority on the Write side 0x0: Channel has low priority on the write side during the arbitration process. 0x1: Channel has high priority on write sided during the arbitration process.	RW	0
25	BUFFERING_DISABLE	This bit allows to disable the default buffering functionality when transfer is source synchronized. 0x0: Buffering is enabled across element/packet when source is synchronized to element, packet, frame or blocks. 0x1: Buffering is disabled across element/packet when source is synchronized to element, packet, frame or blocks.	RW	-

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
24	SEL_SRC_DST_SYNC	Specifies that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request 0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register. 0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register.	RW	-
23	PREFETCH	Enables the prefetch mode 0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffered and pipelined between DMA requests. 0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronized. It is software user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported.	RW	0
22	SUPERVISOR	Enables the supervisor mode 0x0: Supervisor mode is disabled. 0x1: Supervisor mode is enabled.	RW	0
21	RESERVED	Reserved for non-GP devices	RW	0
20:19	SYNCHRO_CONTROL_UPPER	Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel DMA4_CCRi[4:0]) Used in conjunction, as 2 MSB, with the 5 bits of the synchro channel bit field.	RW	0b00
18	BS	Block synchronization This bit used in conjunction with the fs to see how the DMA request is serviced in a synchronized transfer.	RW	-
17	TRANSPARENT_COPY_ENABLE	Transparent copy enable 0x0: Transparent copy mode is disabled. 0x1: Transparent copy mode is enabled.	RW	-
16	CONST_FILL_ENABLE	Constant fill enable 0x0: Constant fill mode is disabled. 0x1: Constant fill mode is enabled.	RW	0
15:14	DST_AMODE	Selects the addressing mode on the Write Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
13:12	SRC_AMODE	Selects the addressing mode on the Read Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
11	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
10	WR_ACTIVE	Indicates if the channel write context is active or not Read 0x0: Channel is not active on the write port. Read 0x1: Channel is currently active on the write port.	R	0
9	RD_ACTIVE	Indicates if the channel read context is active or not Read 0x0: Channel is not active on the read port. Read 0x1: Channel is currently active on the read port.	R	0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
8	SUSPEND_SENSITIVE	Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions.	RW	0
7	ENABLE	Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled. 0x1: The logical channel is enabled.	RW	0
6	READ_PRIORITY	Channel priority on the read side 0x0: Channel has low priority on the read side during the arbitration process. 0x1: Channel has high priority on read sided during the arbitration process.	RW	0
5	FS	Frame synchronization This bit used in conjunction with the BS to see how the DMA request is serviced in a synchronized transfer FS = 0 and BS = 0: An element is transferred once a DMA request is made. FS = 0 and BS = 1: An entire block is transferred once a DMA request is made. FS = 1 and BS = 0: An entire frame is transferred once a DMA request is made. FS = 1 and BS = 1: A packet is transferred once a DMA request is made. All these different transfers can be interleaved on the port with other DMA requests.	RW	-
4:0	SYNCHRO_CONTROL	Channel synchronization control This bit field used in conjunction with the second_level_ synchro_control_upper (as 2 MSB) 0000000 : Is reserved for non synchronized LCH transfer xxxxxxx (from 1 to 127)There are 127 possible DMA request to assign to any LCH. **Note:** The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, DMA4_CCR[4:0] SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1).	RW	0b00000

Interrupt Controllers

This chapter describes the interrupt controllers (INTCs) in the device.

NOTE: Some of the interrupt controllers features, primarily those concerning the device I/O pads and the interrupt controllers integration, are not available in all OMAP54xx devices.

For details, see , *OMAP543x Family and Device Identification*, in Chapter 1, *Introduction*, and the corresponding TRM appendix and device data manual.

Topic **Page**

17.1 Interrupt Controllers Overview 3793
17.2 Interrupt Controllers Environment 3795
17.3 Interrupt Controllers Integration 3797
17.4 Interrupt Controllers Functional Description 3804
17.5 Interrupt Controllers Register Manual 3805

17.1 Interrupt Controllers Overview

The device provides three INTC modules, which handle interrupts at the device level:

- Microprocessor unit (MPU) subsystem (dual Cortex™-A15) interrupt controller (INTC_MPU): This INTC module is a single functional unit that is integrated in the Cortex-A15 multiprocessor core alongside Cortex-A15 processors. It provides:
  - 160 hardware interrupt inputs
  - Generation of interrupts by software
  - Prioritization of interrupts
  - Masking of any interrupts
  - Distribution of the interrupts to the target Cortex-A15 processor(s)
  - Tracking the status of interrupts
  - Support for virtualization extensions
  - Wake-up generator (WUGEN_MPU) module on external and local interrupts
- Digital signal processor (DSP) subsystem interrupt controller (INTC_DSP): This module is a specific combination of wake-up generator (WUGEN_DSP) and the C64x+ INTC_DSP. The INTC_DSP is used in the device but not described in detail in this chapter. For detailed information about this module, see DSP Subsystem.
- Interrupt processor unit (IPU) subsystem (dual Cortex-M4) interrupt controller (INTC_IPU): This module is also called nested vectored interrupt controller (NVIC) and is integrated within each Cortex-M4 core so the different interrupt lines are directly connected to each core. The interrupt mapping is the same for the two cores to facilitate parallel processing. INTC_IPU supports:
  - 64 external interrupts (in addition to 16 Cortex-M4 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
  - Low-latency exception and interrupt handling
  - Prioritization and handling of exceptions
  - Control of the local power management
  - Debug accesses to the processor core
  - Wake-up generator (WUGEN_IPU) module on external interrupts, coming from device peripherals

17.2 Interrupt Controllers Environment

This section describes the environment of the INTC application fields (in other words, external connections).

Figure 17-2 shows the relationship between the module and external interrupts.

Figure 17-2. Interrupts From External Devices

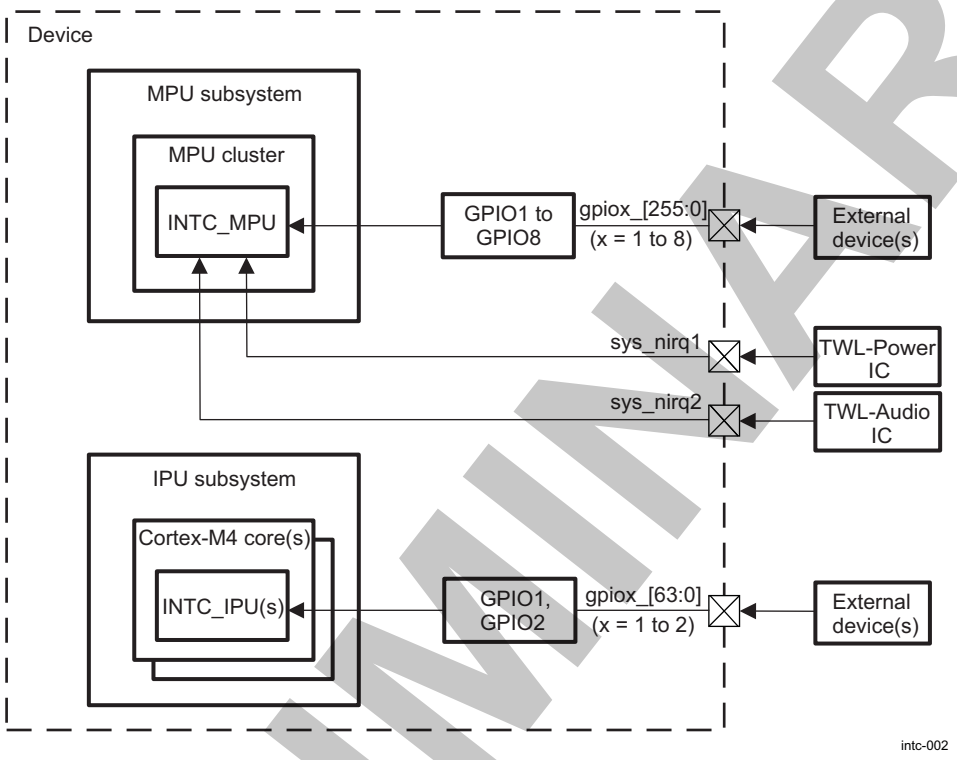

Table 17-1 describes the I/O signals that can be used by external devices to generate interrupts to the INTC_MPU or INTC_IPU.

Table 17-1. Interrupt Controllers I/O Signals

Signal Name	I/O[1]	Reset Value	Description	INTC_MPU	INTC_IPU
sys_nirq1	I	1	TWL-Power IC can use this pin to generate a system wake-up event to INTC_MPU.	✓	–
sys_nirq2	I	1	TWL-Audio IC can use this pin to generate a system wake-up event to INTC_MPU.	✓	–

(1) I = Input, O = Output

Table 17-1. Interrupt Controllers I/O Signals (continued)

Signal Name	I/O[1]	Reset Value	Description	INTC_MPU	INTC_IPU
gpio1_[31:0]	I/O	–	External devices can use GPIO modules to generate interrupts to INTC_MPU or INTC_IPU. There are eight dedicated interrupt lines (for GPIO1 to GPIO8) to the INTC_MPU and two dedicated interrupt lines (for GPIO1 and GPIO2) to the INTC_IPU. Each GPIO module can generate a single interrupt whenever there is at least one event in any one of the configured 32 GPIO inputs. For more information about GPIO interrupt generation, see General-Purpose Interface.	✓	✓

17.3 Interrupt Controllers Integration

The INTC_MPU is integrated inside the Cortex-A15 MPCore (MPU cluster). For more information about INTC_MPU integration, see Section 4.2, *Dual Cortex-A15 MPU Subsystem Integration*, in Chapter 4, *Dual Cortex-A15 MPU Subsystem*.

The INTC_IPU is integrated inside each Cortex-M4 core. For more information about INTC_IPU integration, see Section 7.2, *Dual Cortex-M4 IPU Subsystem Integration*, in Chapter 7, *Dual Cortex-M4 IPU Subsystem*.

17.3.1 Interrupts Mapping

NOTE: All device peripherals interrupts (external to the MPU, DSP, and IPU subsystems) are active-high, level sensitive.

CAUTION

A single interrupt source can be physically mapped to multiple INTCs (MPU, DSP, and IPU subsystems). With multiple-mapped interrupts, TI strongly recommendeds unmasking each interrupt source in only one INTC at a time.

17.3.2 Interrupt Requests to INTC_MPU

Table 17-2 shows the INTC_MPU interrupt mapping.

Table 17-2. INTC_MPU Interrupt Mapping

Interrupt Line (Destination)	Interrupt Line (Source)	Root Source Module	Description
MPU_IRQ_0	MPU_CLUSTER_IRQ_INTERR	MPU_CLUSTER	Illegal writes to interrupt controller memory map region[1]
MPU_IRQ_1	CS_CTI_MPU_C0_IRQ	CS_CTI_MPU_C0	TRIGOUT[6] of Cross Trigger Interface 0 (CTI0)[1]
MPU_IRQ_2	CS_CTI_MPU_C1_IRQ	CS_CTI_MPU_C1	TRIGOUT[6] of Cross Trigger Interface 1 (CTI1)[1]
MPU_IRQ_3	MPU_CLUSTER_IRQ_AXIERR	MPU_CLUSTER	Error indication for AXI write transactions with a BRESP error condition[1]

17.4 Interrupt Controllers Functional Description

17.4.1 INTC_MPU Functional Description

INTC_MPU is configured to have the following interrupt sources:

- 16 software-generated interrupts (SGIs): ID[15:0]
- 7 private peripheral interrupts (PPIs): ID[31:25]
- 160 shared peripheral interrupts (SPIs): ID[191:32] (rising-edge or high-level sensitive). The interrupt mapping of these interrupts is presented in Table 17-2.

CAUTION

Although the hardware interrupts can be configured to be rising-edge or high-level sensitive in the INTC, the device supports only active-high, level-sensitive configuration.

For more information about the functionality of the INTC_MPU, see ARM *Cortex-A15 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

17.4.2 INTC_IPU Functional Description

The INTC_IPU has the following configuration in the device:

- 64 hardware interrupts/16 levels of priority for each Cortex-M4 core. The interrupt mapping of these interrupts (IPU_IRQ_[79:16]) is presented in Table 17-3.
- The calibration register, which is used to reload the SYSTICK timer to generate a fixed interval, is not supported in the Cortex-M4 core within the IPU subsystem. The TENMS field is not available due to the different frequencies during voltage scaling.
- The SYSRESETREQ reset feature is not supported at the Cortex-M4 processor level. Writing to this bit has no effect.

For more information about the functionality of the INTC_IPU, see *ARM Cortex-M4 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

Control Module

This chapter describes the system control module for the device.

NOTE: Some of the control module features, primarily those concerning the device I/O pads, are not available in all OMAP54xx devices.

For details, see Section 1.5, *OMAP543x Family and Device Identification*, in Chapter 1, *Introduction*, and the corresponding TRM appendix and device data manual.

18.1 Control Module Overview

The control module allows software control of the various static modes supported by the device. It is composed of two control submodules: general control module and device (pad configuration) control module.

The general control module has the following features:

- General status and control
- Hardware observability input/output (I/O) multiplexing
- Standard eFuse logic

The device control module provides the following features:

- Pad functional I/O multiplexing
- Pad pullup and pulldown configuration
- Pad groups associated signal integrity controls
- Complex I/O configuration
- Analog function control
- Device-specific eFuse registers

Both control submodules are split into two instances: the control core instance within the CORE power domain, and the control wake-up instance within the WKUP power domain. For more information about the four control module instances, see Section 18.3, *Control Module Integration*.

Figure 18-1 is an overview of the control module.

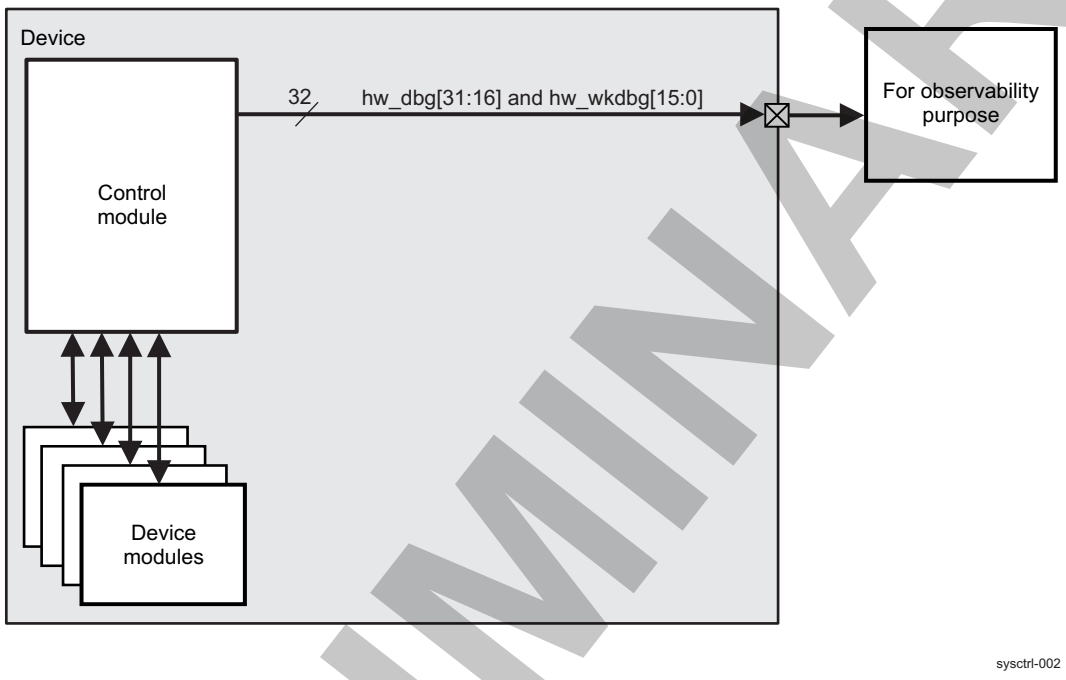
18.2 Control Module Environment

The control module controls the multiplexing of device internal module signals routed to the external pins (hw_dbg[31:0]) for hardware debug purposes. For more information, see Section 18.4.11, *Hardware Observability*, and Section 18.4.8, *PAD Functional Multiplexing and Configuration*. Using the correct pad configuration, the control module maps these pins at the device boundary to observe the internal signals from the power, reset, and clock management (PRCM) module, direct memory access (DMA) requests, and interrupts. Figure 18-2 is an overview of the control module environment.

Figure 18-2. Control Module Environment



18.2.1 Control Module Signals

Table 18-1 lists the control module hardware observability outputs configured to observe the debug signals of the device module. It describes the module signals and specifies their links to functions.

Table 18-1. Control Module I/O Description

Signal	I/O[1]	Description	Reset Value[2]
hw_dbg[31:16] and hw_wkdbg[15:0]	O	32 internal hardware observability signals. hw_dbg[31:16] are mapped to pads in the CORE power domain and hw_wkdbg[15:0] are mapped to pads in the WKUP power domain.	Hi-Z

(1) I = Input; O = Output; I/O = Bidirectional
(2) Hi-Z = High impedance

18.3 Control Module Integration

The control module of the device is on the L4_CORE interconnect. It consists of four module instances:

- General core control module (CTRL_MODULE_CORE)
- General wakeup control module (CTRL_MODULE_WKUP)
- Device core control module (CTRL_MODULE_CORE_PAD)
- Device wakeup control module (CTRL_MODULE_WKUP_PAD)

For more information about the different control module instances, see Table 18-4.

Each of these four module instances has an associated register set and shares one functional clock and one reset signal with the PRCM module. The exception is the general core control module (CTRL_MODULE_CORE), which also receives a secondary functional clock, L3INSTR_TS_GCLK. Table 18-2 describes the signals.

Table 18-2. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
CTRL_MODULE_WKUP	WKUPAON_GICLK	WKUPAON_GICLK	PRCM	L4_WKUP interface/functional clock propagated to the general wkup control module
CTRL_MODULE_WKUP_PAD	WKUPAON_GICLK	WKUPAON_GICLK	PRCM	L4_WKUP interface/functional clock propagated to the device wkup control module
CTRL_MODULE_CORE	L4CFG_L4_GICLK	L4CFG_L4_GICLK	PRCM	L4_CFG interface/functional clock propagated to the general core control module
	L3INSTR_TS_GCLK	L3INSTR_TS_GCLK	PRCM	Functional clock for the three bandgap state-machines instantiated in the general core control module
CTRL_MODULE_CORE_PAD	L4CFG_L4_GICLK	L4CFG_L4_GICLK	PRCM	L4_CFG interface/functional clock propagated to the device core control module
Resets				
CTRL_MODULE_WKUP	WKUPAON_PWRON_RST	WKUPAON_PWRON_RST	PRCM	Internal power-on reset (POR) affecting the general wakeup control module
CTRL_MODULE_CORE	CORE_PWRON_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal POR affecting the general core control module
CTRL_MODULE_WKUP_PAD	WKUPAON_PWRON_RST	WKUPAON_PWRON_RST	PRCM	Internal POR affecting the device wakeup control module
CTRL_MODULE_CORE_PAD	CORE_PWRON_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal POR affecting the device core control module

Table 18-3. Hardware Requests

Interrupt Requests				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Destination**	**Description**
CTRL_MODULE_CORE	MPU_IRQ_126	THERMAL_ALERT	MPU	Interrupt generated by general core control module to the MPU
CTRL_MODULE_CORE	MPU_IRQ_75	PBIAS_IRQ	MPU	Interrupt generated by the PBIAS cell to the MPU

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: For a description of the interrupt sources, see Section 17.3.2, *Interrupt Requests to INTC_MPU*, in Chapter 17, *Interrupt Controllers*.

The control module is reset by the internal POR, which is active low. The PRCM module provides a retention POR signal (CORE_PWRON_RET_RST) duplicated to both of the core control module instances, and a nonretention POR signal (WKUPAON_PWRON_RST) duplicated to each of the two wake-up control module instances in the control module. For more information, see Section 3.5.4, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*. The control module does not respond to a warm reset or to an L4_CORE reset.

The main sequential logic within the system control module is accessible in a register file through the L4_CORE interconnect. The PRCM module provides the L4CFG_L4_GICLK functional clock signal (CD_L4_CFG clock domain) separately to each of the two core control submodules. In addition, the bandgap state-machine, instantiated inside the CTRL_MODULE_CORE receives its functional clock (L3INSTR_TS_GCLK) from the PRCM module. For more information about this signal, see Section 3.6.3.1 , *PRM Clock Source*, in Chapter 3, *Power, Reset, and Clock Management*.

The PRCM module also supplies the WKUPAON_GICLK functional clock signal (CD_WKUPAON clock domain) to each of the two wake-up control module instances. For more information about this signal, see Section 3.6.3.1 , *PRM Clock Source*, in Chapter 3, *Power, Reset, and Clock Management*.

The PRCM module latches the sys_boot[5:0] pad signals at POR and exports them as vector to the SYS_BOOT[5:0] input of the CTRL_MODULE_CORE. It is scanned in the CONTROL_STATUS[5:0] SYS_BOOT bit field.

The thermal management subsystem inside the general core control module delivers one interrupt request (THERMAL_ALERT) to line MPU_IRQ_126 of the MPU subsystem interrupt controller (INTC), and delivers three thermal protection output signals (TSHUT) to the PRCM module, used as warm resets. For more information about the functional outputs of the thermal management control module, see Section 18.4.10.

The PBIAS cell delivers an interrupt request (PBIAS_IRQ) to the MPU_IRQ_75 line of the MPU subsystem INTC. This line is activated when a PBIAS error occurs.

The signal integration of the control module features:

- No IDLE hardware handshake
- No STANDBY hardware handshake
- No wake-up request generation
- No DMA request generation
- Two interrupt requests to the MPU subsystem - THERMAL_ALERT and PBIAS_IRQ
- Three TSHUT used as PRCM warm-reset sources
- Three functional clocks: two clocks in the CFG and one in the WKUP clock domains
- One retention and one nonretention internal power-on-based resets

Figure 18-3 shows the integration of the module in the device.

18.4 Control Module Functional Description

18.4.1 Control Module Block Diagram

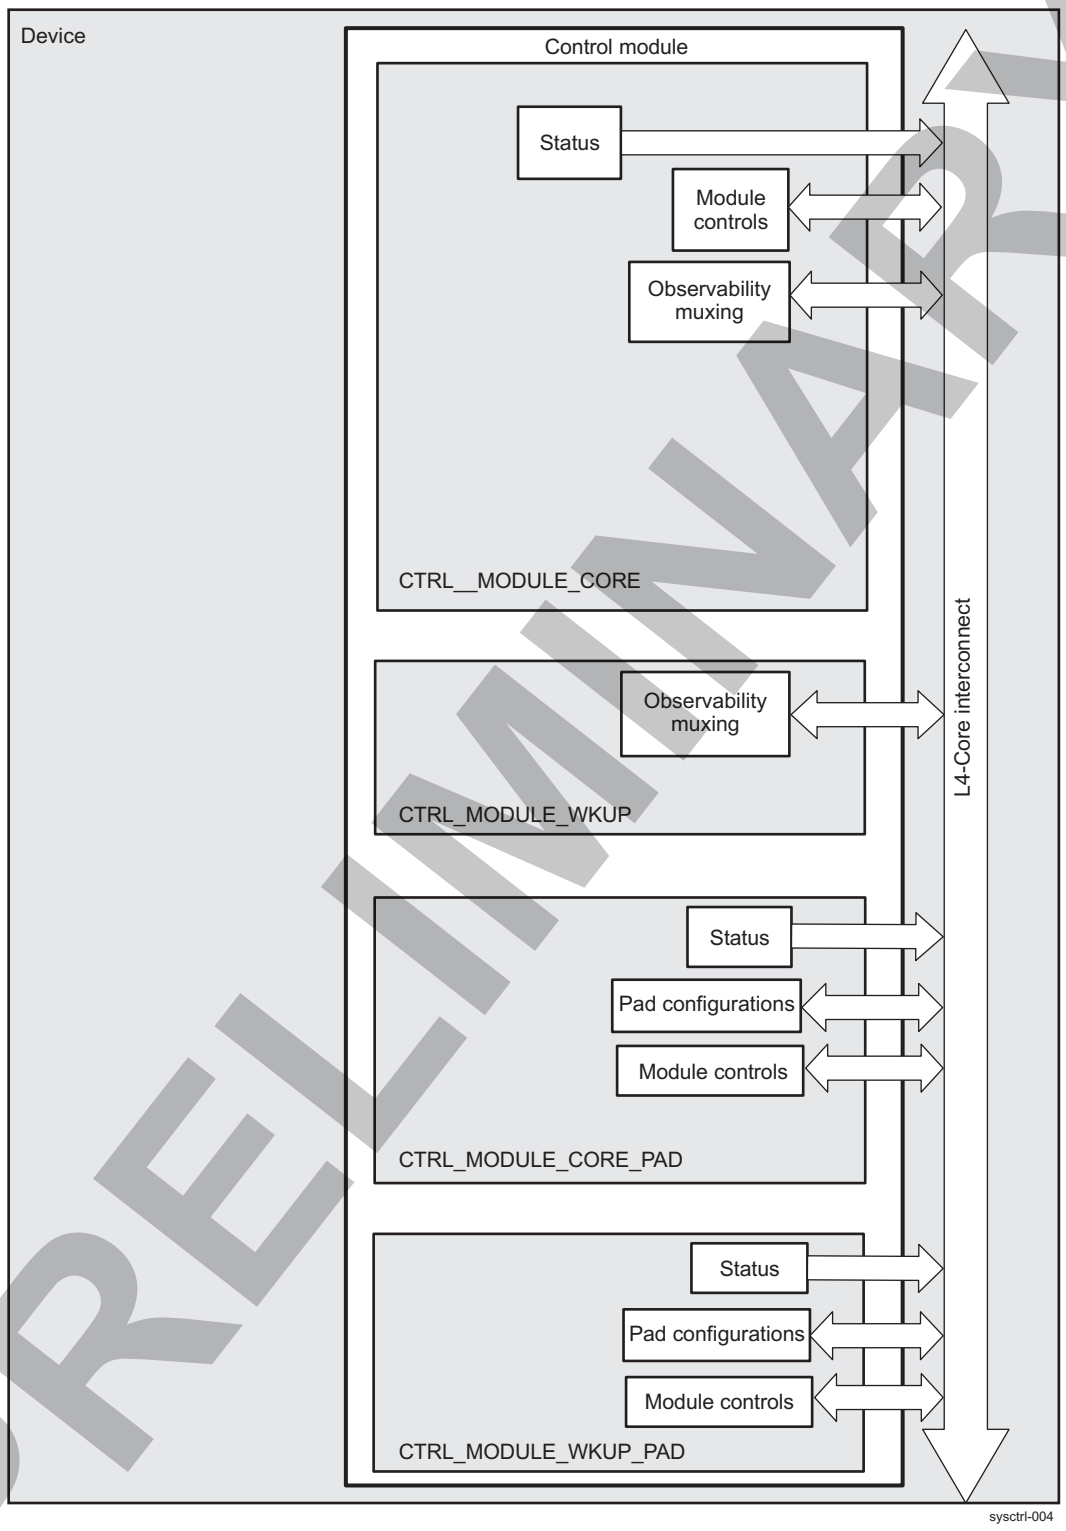
The control module controls the settings of various device modules through the register configuration and internal signals. It also controls the pad configuration, pin functional multiplexing, and the routing of internal signals (such as PRCM signals or DMA requests) to output pads configured for hardware observability.

Figure 18-4 is the control module block diagram.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 18-4. Control Module Block Diagram



PRELIMINARY

The control submodules primarily implement a bank of registers accessible (read and write) by software and some read-only registers that provide status information.

The 32-bit read and write registers in the general control module (CTRL_MODULE_CORE and CTRL_MODULE_WKUP) can be divided into the following classes:

Copyright © 2013, Texas Instruments Incorporated

- Hardware observability registers
- Status and configuration registers
- Boot registers
- eFuse ROM registers
- Miscellaneous functional registers

The 32-bit read/write registers in the device control module (CTRL_MODULE_CORE_PAD and CTRL_MODULE_WKUP_PAD) can be divided into the following classes:

- Pad configuration registers
- Pad groups (not individual per pad) associated registers for signal integrity parameters control (32-bit read/write registers)
- I/O cells associated specific control registers
- Device-specific status and configuration registers
- Miscellaneous functional registers

18.4.2 Control Module Clock Configuration

The L4CFG_L4_GICLK and WKUPAON_GICLK source clocks are internally distributed into two clock paths: the first path directly mirrors the source clock and is an always-running clock. It is used to synchronize and resample some of the module inputs. The other clock path is automatically gated when there is no access to the control module through the L4 interconnect.

There are no PRCM software controls for the L4CFG_L4_GICLK and WKUPAON_GICLK clocks in the control module. There are, however, clock activity status bits in the PRCM module.

The L3INSTR_TS_GCLK has the following software controls located in the PRCM module:

- Status: see in Chapter 3, *Power, Reset, and Clock Management*
- Divider ratio: see in Chapter 3, *Power, Reset, and Clock Management*

18.4.3 Control Module Software Reset

The control module is not sensitive to software reset.

18.4.4 Control Module Power Management

18.4.4.1 Retention

The control module CORE instances are fully built with retention flip-flops (RFFs) and are powered in the CORE power domain; thus, they can be in active or retention mode. In contrast to the core control instances, the control wake-up instances are always powered and active. For more information about the device low-power states, see Section 3.1.1, *Device Power-Management Architecture Building Blocks*, in Chapter 3*, Power, Reset, and Clock Management*.

18.4.4.2 Power Management Protocols

The control module, which is slave on the L4 interconnect, does not support standby or idle mode protocols.

18.4.5 Hardware Requests

The control module does not generate DMA or wake-up requests. The general core control module generates one IRQ (THERMAL_ALERT) to the MPU (MPU_IRQ_126 line). For more information, see Section 17.3.2, *Interrupt Requests to INTC_MPU*.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

18.4.6 Control Module Initialization

The control module responds only to the internal POR and device type. At power on, reset values for the registers define the safe state for the device. In the initialization mode, only modules to be used at boot time are associated with the pads. Other module inputs are internally tied and outputs pads are turned off. After POR, software must set the pad functional multiplexing and configuration registers to the desired values according to the requested device configuration. For more information, see Section 28.1, *Initialization overview*.

The CONTROL_STATUS[5:0] SYS_BOOT bit field reflects the state of the sys_boot pads captured at POR in the PRCM module.

18.4.7 Control Module Instances

18.4.7.1 General Core Control Module Instance

The CTRL_MODULE_CORE instance contains most of the control logic that provides the hardware observability features for different digital phase-locked loop (DPLL) clockout and DPLL-specific signals, DMA requests, IRQs, and other internal hardware signals. The general core control provides the system boot decoding logic and has control over the standard eFuse settings. The system configuration registers, specific function controls, and some peripheral control and status registers are also mapped there.

The following register sets are available within the CTRL_MODULE_CORE:

- Observability control registers:
  - CONTROL_HWOBS_CONTROL
  - CONTROL_DEBOBS_FINAL_MUX_SEL
  - CONTROL_CONF_SDMA_REQ_SELx
  - CONTROL_CONF_CLK_SELx (where x = 0 to 2)
  - CONTROL_CONF_DPLL_X_SEL (where X = FREQLOCK, TINITZ, PHASELOCK, TENABLE, TENABLEDIV, BYPASSACK, IDLE)
  - CONTROL_CONF_DPLLCTRL_X_SEL (where X = PLLLOCK, PLLRECAL, STOPCLOCK, STOPCLOCKACKZ)
  - CONTROL_CONF_MMCX_X_SEL (where X = ADPIDLE, OCPL4IDLEREQ, OCPL3MWAIT, PIRFFRET, OCPL4SIDLEACKO1, OCPL4SIDLEACKO0, OCPL3MSTANDBYO, SWAKEUP)
- Part of the debug view channel selection registers: CONTROL_CORE_CONF_DEBUG_SEL_TST_X
- MMU address translation-related registers: CONTROL_CORTEX_M4_MMUADDRTRANSLTR and CONTROL_CORTEX_M4_MMUADDRLOGICTR
- Standard fuse registers: CONTROL_STD_FUSE_X
- Control status register: CONTROL_STATUS
- Different peripheral control registers.

18.4.7.2 General Wake-Up Control Module Instance

The following registers are associated with the CTRL_MODULE_WKUP instance:

- Register with spare bits: CONTROL_OCPREG_SPARE
- Part of the debug view channel selection registers: CONTROL_CONF_DEBUG_SEL_TST_X

18.4.7.3 Device Core Control Module Instance

The CTRL_MODULE_CORE_PAD instance provides the device-specific pad control features, such as pullup and pulldown I/O configuration and pad functional multiplexing. Wake-up control and status features are also subjects of the device core control.

The following registers are associated with this module:

- Different peripheral pad mode configuration and wake-up status and configuration registers, such as:
  - CONTROL_CORE_PAD0_X_PAD1_Y

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

  - CONTROL_PADCONF_WAKEUPEVENTx
  - CONTROL_SMARTxIO
- Peripheral pad voltage-level control register: CONTROL_PADCONF_MODE
- Miscellaneous controls for different device interface modules: CONTROL_X registers, such as the CONTROL_EMIF register (including the CONTROL_EFUSE registers)

18.4.7.4 Device Wake-Up Control Module Instance

Configuration registers for all pads linked to the wake-up voltage domain are in the CTRL_MODULE_WKUP instance. The registers instantiated are:

- CONTROL_WKUP_PAD0_X_PAD1_Y registers for configuring FREF clock oscillator pads, reset signals, and power mode pad configurations
- Peripheral pad voltage-level control register: CONTROL_WKUP_PADCONF_MODE

Section 18.6.1, *Control Module Instance Summary*, shows the memory size and base addresses assigned to the different control module instances.

18.4.8 Pad Functional Multiplexing and Configuration

After POR, software must set the pad functional multiplexing and configuration registers to the desired values according to the requested device configuration. The configuration is controlled by pads or a group of pads. Each configurable pad has its own configuration register for pullup and pulldown control and for assignment to a given module.

Two sets of 32-bit registers provide the pad functional multiplexing and configuration feature of the control module. The first set of registers (CONTROL_CORE_PAD0_X_PAD1_Y) configures the pads in the CORE power domain. The second set of registers (CONTROL_WKUP_PAD0_X_PAD1_Y) configures the pads in the WKUP power domain.

The pad configuration as defined in this module is used in the IO_CTRL logic along with the gating and protection features. The gating feature is implemented for the output pads. The protection feature is implemented for input lines. These features implement additional control and multiplexing capabilities hard-wired in the IO_CTRL logic and driven by the state and/or logic of the internal device.

The gating feature allows forcing an output pad to a fixed value (Z, pullup, pulldown, 1, 0) or to a given internal signal. Each gating command is defined with a logic equation and the output state or value to be set on the pad when the logic equation is True.

The protection feature provides control on each input line of the control module when no pad is assigned to this input (protected value). When POR is released, the value on the pad is driven by the default configuration of the control module. This configuration is usually aligned with the default value selected on the I/O cell. The protected value can be logical level (0 or 1) or a signal from a pad; it is selected when none of the pad_x.MuxMod selects a device input.

Each 32-bit pad configuration register controls two pads: the first pad is controlled by the 16 least-significant bits (LSBs), and the second pad is controlled by the 16 most-significant bits (MSBs); thus, one pad configuration register provides control for two different pins. After POR, software sets the pad functional multiplexing and configuration registers to the requested device pad configurations. Data written in these registers directly commands the multiplexing of the pad configuration logic. Figure 18-5 shows the 16-bit-wide pad configuration register field associated with each pin.

PRELIMINARY

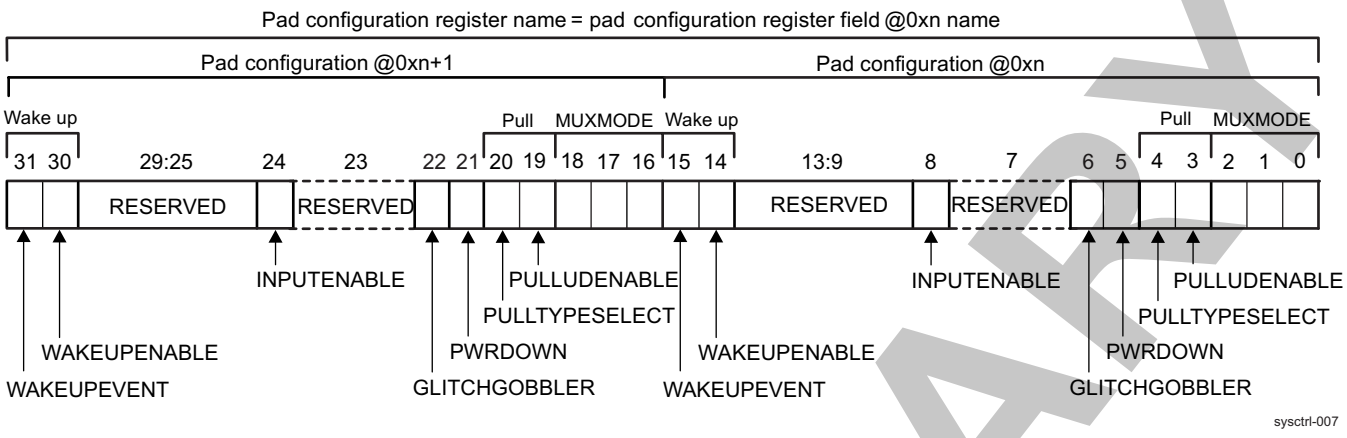
Figure 18-5. Pad Configuration Register Functionality



NOTE: These registers can be accessed using 8-, 16-, and 32-bit operations.

The functional bits of a pad configuration register field are divided into the following seven fields:

- MUXMODE (3 bits) defines the multiplexing mode applied to the pad. A mode corresponds to the selection of the function mapped on the pad with seven (0 to 6) possible functional modes for each pad.
- PULL (2 bits) for combinational pullup and pulldown configuration:
  - PULLTYPESELECT: Pullup and pulldown type selection for the pad
  - PULLUDENABLE: Enables pullup and pulldown feature for the pad
- INPUTENABLE (1 bit) drives an input enable signal to the I/O CTRL.
  - INPUTENABLE = 0: Input disable. Pad is configured only in output mode.
  - INPUTENABLE = 1: Input enable. Pad is configured in bidirectional mode.
- Wake-up bits (2 bits):
  - WAKEUPENABLE: Enable wake-up detection on input.
  - WAKEUPEVENT: Wake-up event status for the pad
- PWRDOWN (1 bit): The Power Down setting for the corresponding pad
  - PWRDOWN = 0: The I/O cell is powered.
  - PWRDOWN = 1: The I/O cell is not powered.
- GLITCHGOBBLER (1 bit): Enables/Disables glitch filtering
  - GLITCHGOBBLER = 0: The I/O cell does not filter outside glitches.
  - GLITCHGOBBLER = 1: The I/O cell filters outside glitches.

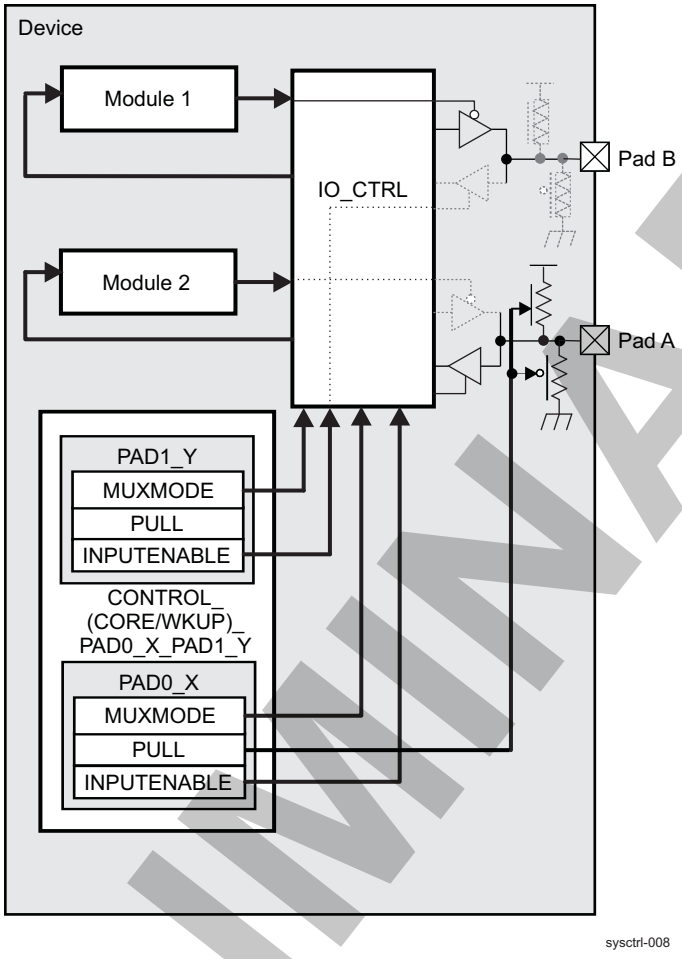
NOTE: The GLITCHGOBBLER bit is available only in several pad configuration registers at bit positions [22] or [6].

Figure 18-6 shows the pad configuration functionality.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 18-6. Pad Configuration Diagram



The I/O pads are controlled by software by:

- Writing to the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y registers in the device control module for I/O and pullup and pulldown configuration
- Writing to the GPIOi.GPIO_OE registers in the GPIO module for I/O configuration

For more information about the GPIO module, see Section 25.4.8, *General-Purpose Interface Data Input/Output Capabilities*.

NOTE: For the proper functioning of the following modules, the INPUTENABLE bit in the corresponding pad configuration register must be set to 1 for pads configured to drive output clocks:

- GPMC
- I2Ci
- MMCi
- USB_HOST_HS
- MCPDM

The output clock is driven back and used for retiming of the modules.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: For a correct configuration of each pad direction (input, output, bidirectional), the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y and GPIOi.GPIO_OE registers must be written.

Table 18-5 lists the bit directions of the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y registers.

Table 18-5. Bit Meanings for CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y Registers

Pad Configuration Bit	Bit Meaning	
	0	1
PULLUDENABLE	Not activated	Activated
PULLTYPESELECT	Pulldown	Pullup
INPUTENABLE	Input enable signal is inactive.	Input enable signal is active.
WAKEUPENABLE	Disable I/O wake-up function.	Enable I/O wake-up function.
WAKEUPEVENT	Wake-up event is not detected.	Wake-up event is detected.
MUXMODE bits	See Table 18-6	See Table 18-6
PWRDOWN	The I/O cell is powered.	The I/O cell is not powered.
GLITCHGOBBLER	Glitch filter disable	Glitch filter enable

18.4.8.1 Mode Selection

Table 18-6 lists the multiplexing modes and settings.

Table 18-6. Mode Selection

MUXMODE	Selected Mode
0b000	Primary mode = Mode 0
0b001	Mode 1
0b010	Mode 2
0b011	Mode 3
0b100	Mode 4
0b101	Mode 5
0b110	Mode 6
0b111	Safe mode = Mode 7

The MUXMODE field in the CONTROL_CORE_PAD0_X_PAD1_Y and CONTROL_WKUP_PAD0_X_PAD1_Y registers defines the multiplexing mode applied to the pad. Modes are referred to by their decimal (from 0 to 7) or binary (from 0b000 to 0b111) representation. Functional modes are defined from 0b000 to 0b110; mode 0b111 is referred to as the safe mode.

For most pads, the reset value for the MUXMODE field in the CONTROL_CORE_PAD0_X_PAD1_Y and CONTROL_WKUP_PAD0_X_PAD1_Y registers is 0b111. The exceptions are pads to be used at boot time to transfer data from selected peripherals to the external flash memory.

Mode 0 is the primary mode. When mode 0 is set, the function mapped to the pad corresponds to the name of the pad.

Modes 1–6 are possible modes for alternate functions. On each pad, some modes are used effectively for alternate functions, while other modes are unused and correspond to no functional configuration.

Safe mode (mode 7) avoids any risk of electrical contention by configuring the pad as an input with no functional interface mapped to it. Safe mode is used mainly as the default mode for all pads containing no mandatory interface at the release of POR.

NOTE: When a pad is set into a mux mode that is not defined by pad multiplexing, the pad is actually set undriven (Hi-Z) with potential pullup or pulldown.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

For more information about the configurable mode on each pad, see Table 18-8 and Table 18-9.

NOTE: Pad names are signal names available in mode 0.

18.4.8.2 Pull Selection

There is no automatic gating control to ensure that internal weak pulldown or pullup resistors on a pad are disconnected whenever pad is configured as output. If a pad is always configured in output mode, it is recommended for user software to disable any internal pull resistor tied to it, to avoid unnecessary consumption.

Table 18-7 describes the software controls available for pad internal pullup and pulldown resistors in the control module padconfiguration registers.

Table 18-7. Pull Selection

PULL		Pin Behavior
PULLTYPESELECT	PULLUDENABLE	
0b0	0b0	Pulldown selected but not activated
0b0	0b1	Pulldown selected and activated
0b1	0b0	Pullup selected but not activated
0b1	0b1	Pullup selected and activated

For more information about the pull available on each pad, see Table 18-8 and Table 18-9.

NOTE: Software controls for internal active mode pullups and pulldowns on the lpddr21_x and lpddr22_x pads are available in the CONTROL_LPDDR2CH1_0 and CONTROL_LPDDR2CH1_1 registers, respectively.

Software controls for internal active mode pullups and pulldowns on the usbb1_hsic_x, usbb2_hsic_x, and usbb3_hsic_x pads are available in the CONTROL_SMART3IO_PADCONF_1 register.

18.4.8.3 Pad Multiplexing Register Fields

Table 18-8 and Table 18-9 provide for each pad configuration register field the address offset and associated signal name for each multiplexing mode (as set by the MUXMODE bit field). Mode 0 is always defined. Modes with no signal name are undefined for the given pad. For more information about default pad configuration settings (POR values) for pads in the CORE power domain, see Section 18.6.3, *CTRL_MODULE_CORE_PAD Registers.* For pads in the WKUP power domain, see Section 18.6.5, *CTRL_MODULE_WKUP_PAD Registers*.

NOTE:

- Table 18-8 lists the pad configuration registers instantiated in the WKUP power domain that drive the pads in the WKUP power domain. Table 18-9 lists the pad configuration registers instantiated in the CORE power domain that drive the pads in the CORE power domain.
- In Table 18-8 and Table 18-9, an empty cell indicates that the mode or pull is not available for this pad.

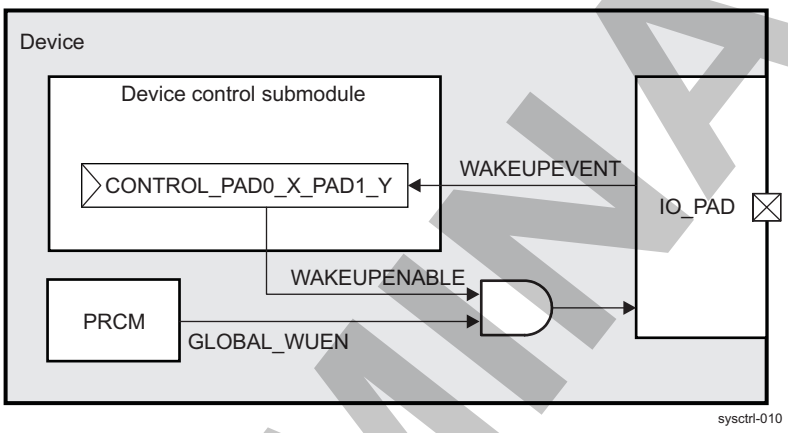
18.4.8.4 Wake-Up Event Detection

In low power mode, wake-up event detection can also be enabled on an input pad. The pad wake-up event is latched in the CONTROL_CORE_PAD0_X_PAD1_Y[31,15] and CONTROL_WKUP_PAD0_X_PAD1_Y[31,15] WAKEUPEVENT bits.

The wake-up scheme is enabled by setting the PRM_IO_PMCTRL[16] GLOBAL_WUEN bit from the PRCM module. The status of the wake-up scheme is transmitted by the WKUP_ENABLE signal. The capability of each I/O pad to detect wake-up events in the device is individually enabled or disabled by writing the CONTROL_CORE_PAD0_X_PAD1_Y[30,14] and CONTROL_WKUP_PAD0_X_PAD1_Y[30,14] WAKEUPENABLE bits.

Figure 18-7 is an overview of wake-up event detection in the device.

Figure 18-7. Wake-Up Event Detection Overview



NOTE: When wake-up detection is enabled for a pad, the pad must be configured as input to avoid contention between the device output buffer and an external driver.

NOTE: Regardless of whether the INPUTENABLE bit is set high or low during active mode, to enable wake-up detection for a pad, user software must set the WAKEUPENABLE bit to 0x1. It is recommended to apply pullup and pulldown resistors at the pad to avoid spurious wake-up detection.

The CONTROL_PADCONF_WAKEUPEVENT_0 through CONTROL_PADCONF_WAKEUPEVENT_6 registers are dedicated 32-bit registers for a separate capture of the WAKEUPEVENT from different pads. Duplication of the CONTROL_CORE_PAD0_X_PAD1_Y[31,15] and CONTROL_WKUP_PAD0_X_PAD1_Y[31,15] wake-up event bits inside these additional registers helps to reduce the software latency when identifying which pad has triggered a wake-up event.

For unconnected device pads, safe_mode pad configuration is recommended if available. Table 18-10 summarizes recommendations for the configuration of unconnected pads (in terms of mux mode, input, and output buffer states) for all cases, including those where safe_mode configuration is not available.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 18-10. Recommended Configuration For Unconnected Device Pads

Pad MuxMode Set Features	Power-on reset default configuration		Recommended Unconnected Device Pad Configuration				
Safe Mode Available?	Multiplexed Signal Direction at Pad	Pad State[1]	Multiplexed Signal Direction at Pad	Pad State	Input Buffer Disabled? [2]	Output Buffer Disabled? [3]	MUX Function Selected [4]
Yes	Input	PU	Safe mode	PU	Yes	N/A	Safe mode
Yes	Input	PD	Safe mode	PD	Yes	N/A	Safe mode
Yes	Output	1	Safe mode	PD	Yes	N/A	Safe mode
Yes	Output	0	Safe mode	PD	Yes	N/A	Safe mode
Yes	–	Hi-Z	Safe mode	PD	Yes	N/A	Safe mode
No	Input	PU	Input	PU	Yes	N/A	N/A (default)
No	Input	PD	Input	PD	Yes	N/A	N/A (default)
No	Output	1	Output	1	Yes	N/A	N/A (default)
No	Output	0	Output	0	Yes	N/A	N/A (default)
No	–	Hi-Z	Input	PD	Yes	N/A	N/A (default)

(1) PU = Pullup; PD = Pulldown; Hi-Z = High impedance

(2) Yes: If a certain device pad is left unconnected, its associated pad configuration register INPUTENABLE bit must be explicitly disabled in software (set to 0b0), regardless of pad MUXMODE bit field value.

(3) N/A: There is no software control over the pad associated output buffer in the control module.

(4) SAFE MODE: If a certain pad has a defined safe_mode and is left unconnected in an application, it is recommended to keep its padconfiguration MUXMODE value at 0x7 (that is, safe_mode).
N/A (default): The pad does not have a defined safe_mode. Keeping the default value is recommended.

18.4.9 Extended-Drain I/O and PBIAS Cell

The device primarily supports 1.8-V I/O voltage on its interfaces, with the exception of the MMC/SD/SDIO1 interface, which supports 1.8-V and 3.0-V voltages. The need for embedded extended-drain I/Os on the MMC/SD/SDIO1 interface imposes the use of embedded PBIAS cell SDCARD_PBIAS to provide a 1.8-V or 3.0-V reference.

The SDCARD_PBIAS cell and its associated extended-drain I/O cell are software-controlled by bits in the CONTROL_PBIAS and CONTROL_HYST_1 registers of the device core control module.

Figure 18-8 shows the functional block diagram with the connections between the PBIAS cell and the extended-drain I/O cell.

Table 18-11. PBIAS Cell and Extended-Drain I/O Pin CONTROL_PBIAS Bit Control

Control Signals for PBIAS Cell and Extended-Drain I/O Cell	Description
SDCARD_BIAS_PWRDNZ	Protects the SDCARD_PBIAS cell when the SDCARD_VDDS supply voltage is not stable. Software must keep this signal to 0b0 whenever this voltage ramps up/down or changes. When this bit is set to 0, the PBIAS output voltage is equal to the SDCARD_VDDS voltage and the PBIAS supply detector is disabled.
SDCARD_IO_PWRDNZ	Protects the SDCARD extended-drain I/O cell when the SDCARD_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SDCARD_VDDS supply voltage ramps up/down or changes. When this bit is set to 0, the pad is floating.
SDCARD_BIAS_VMODE	Controls the SDCARD_VDDS voltage level. The default state of this bit is HIGH, indicating that the voltage level SDCARD_VDDS is 3.0 V.
SDCARD_BIAS_HIZ_MODE	When SDCARD_BIAS_HIZ_MODE is set to 1, the PBIAS output is in high impedance. SDCARD_BIAS_ERROR is automatically set to 1 when SDCARD_BIAS_HIZ_MODE is set to 1. When SDCARD_BIAS_HIZ_MODE is set to 0, SDCARD_PBIAS cell is in normal operation mode.
SDCARD_BIAS_SUPPLY_HI_OUT	Output from the internal SDCARD_PBIAS voltage supply detector, which indicates whether the SDCARD_VDDS supply is 3.0 V or 1.8 V
SDCARD_BIAS_VMODE_ERROR	Indicates whether the software-programmed voltage level of the SDCARD_PBIAS cell matches the SDCARD_BIAS_SUPPLY_HI_OUT output signal during normal operation
SDCARD_HYST	Hysteresis enabling/disabling for the extended-drain I/O cell input buffer.
SDCARD_IC	Impedance control for the extended-drain I/O cell output buffer.
V1V8_SIGEN	Controls the SDCARD_VDDS voltage level. The default state of this bit is LOW, indicating that the voltage level SDCARD_VDDS is 3.0 V.
DS_SEL	Drive strength (impedance) control for extended-drain I/O cell output buffer

NOTE: When MUXMODE is set to 0 (sdcard_i signals are selected), then the CONTROL_PBIAS[21] SDCARD_BIAS_VMODE and CONTROL_HYST_1[30:29] SDCARD_IC bits do not apply. In this case the voltage level and drive strength are controlled through the MMC1.MMCHS_AC12[19] V1V8_SIGEN and MMC1.MMCHS_AC12[21:20] DS_SEL bits, respectively.

Table 18-12 lists the power supplies for PBIAS and the extended-drain I/O cells.

Table 18-12. Power Supplies

Power Supply Name	Description
VDD2	Core voltage supply
SDCARD_VDDS	SDCARD I/O cell supply voltage nominal 1.8 V/3.0 V
VDDS	1.8-V supply for the input buffer

18.4.9.1 PBIAS Cell

The SDCARD_PBIAS cell provides a bias for the MMC/SD/SDIO1 extended-drain I/O cell used with high voltage for the MMC/SD/SDIO1 interface. This PBIAS cell provides a voltage reference (PBIAS voltage) for biasing extended drain in the MMC/SD/SDIO1 cell. In addition to generate the bias voltage, the cell can detect the supply voltage (SDCARD_VDDS) value (1.8 V or 3.0 V) and update, with its status, the CONTROL_PBIAS[24] SDCARD_BIAS_SUPPLY_HI_OUT bit. However, this is possible when the voltage reaches its steady state (the internal PBIAS voltage detector is enabled only when the SDCARD_BIAS_PWRDNZ signal is set to 0b1).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

CAUTION

A PBIAS cell lets the peripheral associated with its corresponding extended-drain I/O cells support 1.8-V and 3.0-V voltages. A PBIAS cell is not part of a peripheral, but part of the device I/Os to which this peripheral is internally connected. These device I/Os are not exclusive to one peripheral; through I/O multiplexing they can be connected to other internal signals. It is necessary to configure the PBIAS to enable the I/Os, regardless of how I/O multiplexing is configured for these device I/Os.

18.4.9.2 Extended-Drain I/O

The following MMC1 interface signals (selected when MuxMode = 0) use the device I/Os associated with the SDCARD extended-drain I/O cell:

- sdcard_clk
- sdcard_cmd
- sdcard_datai (where i = 0 to 3)

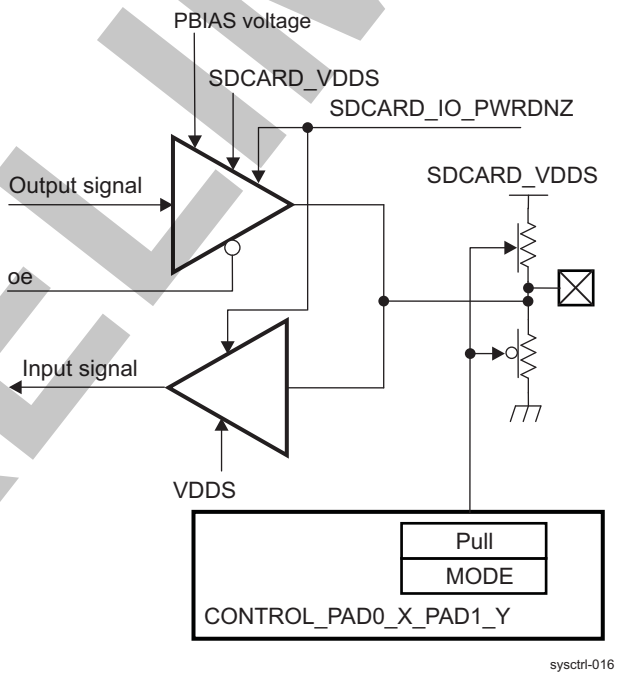
The SDCARD I/O cell is powered externally through the vdds_sdcard pad.

NOTE: The device pads associated with SDCARD I/O cells are also shared with other signals. jtag_tdo, jtag_tdi, uart6_rx, and so forth. are available when MuxMode is different than 0x0. If signals other than sdcard_x are selected, the SDCARD I/O cell must also be configured.

For more information about signal multiplexing, see Table 18-9.

Figure 18-9 shows the extended-drain I/O cells.

Figure 18-9. Extended-Drain I/O



The extended-drain I/O cells have the following I/O signals:

- The output signal, input signal, and oe, which comes from the selected I/O module with the correctly configured MUXMODE field within the corresponding CONTROL_CORE_PAD0_X_PAD1_Y or CONTROL_WKUP_PAD0_X_PAD1_Y register

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: Extended-drain I/Os are muxed I/Os with mode and pullup and pulldown configurations programmable in the control module.

- The PBIAS voltage is a voltage reference for biasing the extended-drain in the SDCARD cell.
- The SDCARD_IO_PWRDNZ signal is used to protect the extended-drain I/O cell when the SDCARD_VDDS voltage is not stable.

NOTE: Software must keep the SDCARD_IO_PWRDNZ signal set to 0b0 whenever the SDCARD_VDDS signal ramps up/down or changes. When SDCARD_IO_PWRDNZ is set to 0, the pad is floating (the pad may not reflect the state of the output signal, and the input signal may not reflect the state of the pad).

- CONTROL_PBIAS[24] SDCARD_BIAS_SUPPLY_HI_OUT is a status bit for the SDCARD_VDDS value and is used to inform the SDCARD I/O cell about the value of the SDCARD_VDDS signal.

For more information about the software configurations of the extended drain I/Os and PBIAS cells, see Section 18.5.1.2.1, *Extended-Drain I/Os and PBIAS Cells Programming Guide.*

NOTE: The device can be supplied by an external power IC. TI provides such a global solution to its customers with the TWL60xx power IC.

If the device is associated with the TWL60xx power IC, before using an extended-drain I/O interface, software must program the TWL60xx to enable SDCARD_VDDS (for the MMC/SD/SDIO1 or muxed I/O modules) and the LDO to provide 1.8-V/3.0-V voltage. This is done by software through the inter-integrated circuit (I^2C™) interface that links the device and the TWL60xx IC.

CAUTION

The power supply voltage, generated from the companion power IC and applied on the vdds_sdcard device pad, must be programmed according to the recommendations for the currently selected I/O module power supply range.

If the application does not want the I/O interface to run at 3.0 V, for 1.8-V activity software must either assert the SDCARD_BIAS_VMODE signal to low or the V1V8_SIGEN signal to high depending on the selected muxmode: in this case, the PBIAS is connected to ground.

Table 18-13 lists the control signals with the corresponding control bits from the CONTROL_PBIAS, CONTROL_HYST_1, and MMC1.MMCHS_AC12 registers to configure the PBIAS and the extended-drain I/O cells. Software can control these signals.

Table 18-13. PBIAS and Extended-Drain I/O Cells Control Signals

Control Signals for PBIAS Cell and Extended-Drain I/O Cell	Bits Used for PBIAS Cell and I/O Cell Configurations for Different I/O Modules	Reset Value
SDCARD_BIAS_PWRDNZ	CONTROL_PBIAS[27] SDCARD_BIAS_PWRDNZ	0
SDCARD_IO_PWRDNZ	CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ	0
SDCARD_BIAS_VMODE	CONTROL_PBIAS[21] SDCARD_BIAS_VMODE	1
SDCARD_BIAS_HIZ_MODE	CONTROL_PBIAS[25] SDCARD_BIAS_HIZ_MODE	0
SDCARD_BIAS_SUPPLY_HI_OUT	CONTROL_PBIAS[24] SDCARD_BIAS_SUPPLY_HI_OUT	0
SDCARD_BIAS_VMODE_ERROR	CONTROL_PBIAS[23] SDCARD_BIAS_VMODE_ERROR	0
SDCARD_HYST	CONTROL_HYST_1[31] SDCARD_HYST	1
SDCARD_IC	CONTROL_HYST_1[30:29] SDCARD_IC	0x0
DS_SEL	MMC1. MMCHS_AC12[21:20] DS_SEL	0x0
V1V8_SIGEN	MMC1. MMCHS_AC12[19] V1V8_SIGEN	0

PRELIMINARY

The PBIAS cell supports two ranges of SDCARD_VDDS: 1.8 V, typical for low-voltage applications, and 3.0 V, typical for high-voltage applications. For each supply voltage range, the PBIAS cell generates suitable bias voltage (PBIAS) for the extended-drain I/O cell.

CAUTION

The PBIAS cell must be programmed according to peripheral power supply voltage. See Table 18-14.

Table 18-14. Voltage Configuration(1)

PBIASVMODE Configuration	SDCARD_VDDS Voltage	Type of Operation
1.8 V	1.8 V	Normal 1.8-V operation
1.8 V	3.0 V	Damaging configuration(2)
3.0 V	1.8 V	Degraded functionality(2)
3.0 V	3.0 V	Normal 3.0-V operation

(1) For damaging configuration, hardware system protection is provided to prevent deterioration of the associated extended-drain I/Os.

(2) These modes must not be used.

Once the SDCARD_VDDS supply is stable, software can release SDCARD_BIAS_PWRNDZ and SDCARD_IO_PWRDNZ bits setting them high. Setting SDCARD_BIAS_PWRNDZ to 0b1 powers-up the PBIAS cell and it starts to generate the bias voltage. During the completion process the corresponding I/Os cannot be used to transmit data. If the voltage level is set correctly (compared with supply detector output and found to be the same), then bias voltage is generated based on this value.

NOTE: In the case of a damaging configuration, hardware system protection prevents deterioration of the associated extended-drain I/Os.

CAUTION

The following requirements are critical for an extended-drain I/O cell:

- The SDCARD_BIAS_VMODE or V1V8_SIGEN bit must be defined before the SDCARD_IO_PWRNDZ bit is made high (cell is brought out of power-down mode).
- The default state of SDCARD_BIAS_VMODE bit is high (indicates 3.0-V operation).
- The default state of the MMC1.MMCHS_AC12[19] V1V8_SIGEN bit is low (indicates 3.0-V operation).
- The SDCARD_IO_PWRNDZ bit must be kept low whenever the SDCARD_VDDS supply ramps up/down or changes. This can be damaging.

18.4.9.3 PBIAS Error Generation

If the programmed PBIAS voltage and supply detector output are unequal, it takes 4 µs for the comparator to process the inputs and generate the SDCARD_BIAS_VMODE_ERROR flag.

Table 18-15 summarizes the generation of the PBIAS error signal (SDCARD_BIAS_VMODE_ERROR of the SDCARD_PBIAS cell), which depends on the various CONTROL_PBIAS bit combinations. The shaded row in the table indicates a condition that could cause a reliability issue if not detected. To prevent this reliability issue, the PBIAS voltage is tied to SDCARD_VDDS when the PBIAS error signal is high. This condition disables the I/Os.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: Although asserting SDCARD_BIAS_VMODE_ERROR to 1 ensures that PBIAS voltage is equal to SDCARD_VDDS, this does not completely protect the I/O cells. It is recommended that all the I/Os are powered down, thus setting the CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ bit to 0b0 by software as soon as CONTROL_PBIAS[23] SDCARD_BIAS_VMODE_ERROR = 0b1.

Table 18-15. PBIAS Error Signal Truth Table

Programmed voltage level		PWRDNZ Bits	SDCARD_BIAS_HIZ_MODE	SDCARD_BIAS_SUPPLY_HI_OUT	SDCARD_BIAS_VMODE_ERROR
SDCARD_BIAS_VMODE (MUXMODE ≠ 0)	V1V8_SIGEN (MUXMODE = 0)				
0	1	0	X	0	0
0	1	1	0	0	0
0	1	1	0	1	1
X	X	1	1	X	1
1	0	0	X	0	0
1	0	1	0	0	1
1	0	1	0	1	0

NOTE: SDCARD_BIAS_VMODE_ERROR = 0b1: The programmed voltage level is not the same as SDCARD_BIAS_SUPPLY_HI_OUT, or Hi-Z mode is selected.

SDCARD_BIAS_VMODE_ERROR = 0b0: The programmed voltage level is the same as SDCARD_BIAS_SUPPLY_HI_OUT, or it is not considered (SDCARD_PWRDNZ = 0b0).

The SDCARD_BIAS_VMODE_ERROR signal output is mapped to the MPU subsystem INTC. The interrupt line MPU_IRQ_75 is activated when an error occurs. For more information about the MPU INTC registers and their description, see the *ARM Cortex-A15 MPCore Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

The CONTROL_PBIAS[23] SDCARD_BIAS_VMODE_ERROR bit also indicates whether this kind of error occurs.

18.4.9.4 Critical Timing Requirements

It is critical that SDCARD_BIAS_PWRDNZ and SDCARD_IO_PWRDNZ bits are deasserted (changed from 0 to 1) only after SDCARD_VDDS power supply voltage is stable in the device. The cells support only the case where the 1.8-V input buffer supply voltage VDDS ramps up before VDD2 (core voltage). This power-up sequence is automatically provided upon POR by hardware in the device. Take care to ensure that the externally provided SDCARD_VDDS voltage (1.8 V/ 3 V) is powered up only after VDD2 and VDDS reach their steady state.

Figure 18-10 shows the only possible power-up sequence, as well as the expected behavior of PWRNDZ mode-related bit with regard to supplying voltage ramp up.

Figure 18-10. VDDS Ramps Up Before VDD2

18.4.10 Bandgap Voltage and Temperature Sensor

The device supplies a voltage reference and a temperature sensor feature that are gathered in the bandgap voltage and temperature sensor (VBGAPTS) module. The bandgap provides current and voltage reference for its internal circuits and other analog IP blocks. The analog-to-digital converter (ADC) produces an output value that is proportional to the silicon temperature. There are three bandgaps: one for MPU, one for GPU and one for device die center.

The main features of the VBGAPTS modules are:

- A constant voltage reference output
- Five constant current reference outputs
- Nominal analog supply
- Small ADC with 10-bit digital output

Three small finite state-machines (FSMs) (bandgap FSMs) are instantiated inside the general core control module to help the three VBGAPTS cells accomplish different measurement modes (see Section 18.4.10.2, *Temperature Sensor*). In addition, three sets of two programmable comparator blocks inside the general core control module post-process the converted data and provide the following outputs:

- Thermal alert programmable comparator outputs
- Thermal shutdown nonprogrammable comparator outputs

Figure 18-11 shows the functional block diagram of the bandgap and the temperature sensor module.

Figure 18-11. Functional Block Diagram

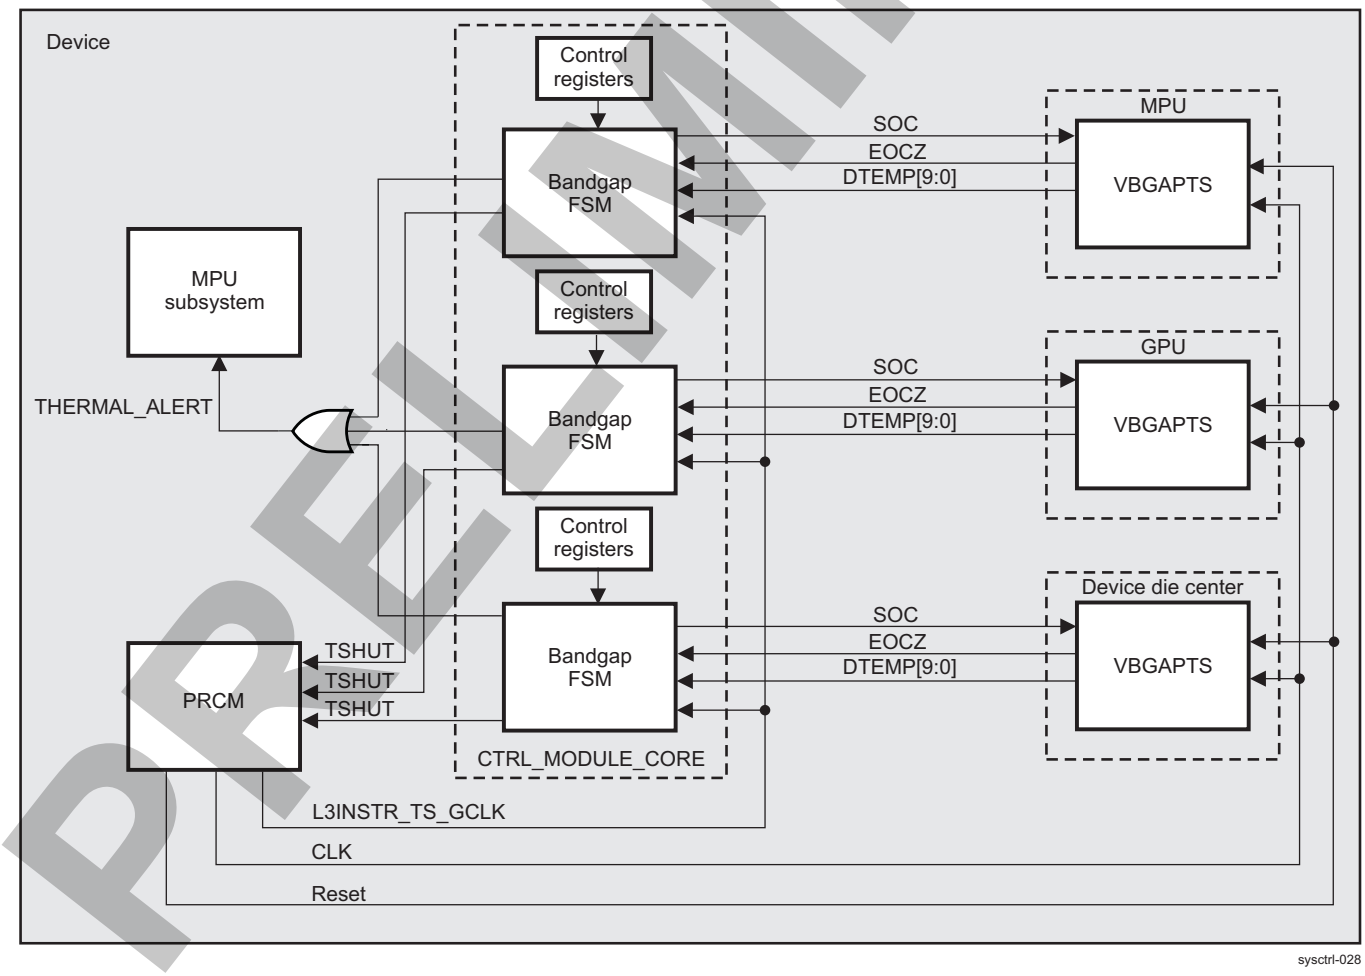

Table 18-16 describes the I/O signals, some of which (SOC, EOCZ, DTEMP[9:0]) build the interface between the VBGAPTS modules and the bandgap state-machines of the general core control module.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 18-16. Bandgap Voltage and Temperature Sensor Signal Description

Pin	I/O[1]	Description
SOC	I	Start of Conversion signal. A transition to high starts a new ADC conversion cycle. This signal is automatically generated by the bandgap FSM.
EOCZ	O	End of Conversion signal. When low, the signal indicates that the value of DTEMP[9:0] is valid.
DTEMP[9:0]	O	Temperature data from the temperature sensor. This value is valid when EOCZ is low.
CLK	I	Functional clock in the range (500 kHz - 5 MHz) from the WKUP power domain used by the temperature sensor during temperature conversion

(1) I = Input; O = Output; I/O = Bidirectional

All the configuration signals of the VBGAPTS temperature conversion logic are available through the CONTROL_TEMP_SENSOR_MPU, CONTROL_TEMP_SENSOR_MM, and CONTROL_TEMP_SENSOR_CORE registers.

NOTE: For more information about all of the configuration registers related to temperature sensor control, see Table 18-63.

The bandgap state-machines of the general core control module are driven by a dedicated clock (L3INSTR_TS_GCLK) that shares a common PRCM clock source with the VBGAPTS CLK. For more information about the thermal management clocks, see Section 3.1.1, *Device Power-Management Architecture Building Blocks*.

Table 18-17 describes the functional outputs of the two post-processing comparator blocks integrated in the general core control module.

Table 18-17. General Core Control Thermal Logic Outputs Description

Functional Output	Description
THERMAL_ALERT	The three thermal alert outputs from each bandgap FSM are ORed and then mapped as an interrupt in the MPU subsystem. Software uses this interrupt to implement a thermal management policy of the device.
TSHUT	Each of the three general core control module thermal shutdown comparator outputs is mapped as a source of PRCM warm reset signals. These overheat protection signals are high during normal operation and go low during a thermal shutdown event.

The configuration bits of the thermal post-processing logic are in several registers of the general core control module. For more information, see Section 18.4.10.2.2, *Thermal Data Post-Processing Logic*.

18.4.10.1 Bandgap Voltage Reference

The bandgap voltage reference feature provides several constant voltage and current references for its internal circuits and for other analog modules.

The voltage reference signal is a 0.5-V output. This output is used internally by the module and is exported for external modules or tests.

The current reference signals consist of five lines, each of which generates a 1-µA current with a 1.8-V voltage. These lines can be used to bias other modules.

18.4.10.2 Temperature Sensor

The temperature sensor feature is used to convert the temperature of the device into a decimal value coded on 10 bits. An internal ADC, which is part of the device embedded bandgap cell, is used for conversion.

For more information on the thermal sensor operating parameters–temperature range, accuracy, and so on, see the *Temperature Sensor* section of the device data manual.

For more details on the device operating junction temperature ranges under different conditions, see the *Recommended Operating Conditions* section of the device data manual.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

NOTE: The temperature measured at the three temperature sensor locations is lower than the temperature of the hottest spot on the device die. This difference, defined also as the temperature offset between the on-die hottest spot temperature and the temperature registered by the on-die thermal sensors, depends on a number of factors, such as the current system power dissipation, device cooling conditions, etc. For more information regarding the temperature sensor offset values under different conditions, contact your TI representative.

CAUTION

User software must always take care to program thermal alert thresholds at levels which do not exceed the device hottest spot maximum-allowed temperature minus the device temperature sensor offset estimated at current conditions.

The TSHUT signals are connected internally to PRCM pins. The three bandgap state-machines operate in continuous conversion mode.

18.4.10.2.1 Continuous Conversion Mode

The continuous conversion mode follows this sequence:

After reset, each FSM produces a programmable delay which is also used as a main delay between two temperature measurements. After this delay the three FSMs automatically generate SOC pulses which start a temperature conversion. Software can control the main delay between two measurements through the dedicated bit field CONTROL_BANDGAP_MASK[29:28] COUNTER_DELAY. The conversion is complete when the CONTROL_TEMP_SENSOR_MPU[10] BGAP_EOCZ_MPU, CONTROL_TEMP_SENSOR_MM[10] BGAP_EOCZ_MM, and CONTROL_TEMP_SENSOR_CORE[10] BGAP_EOCZ_CORE status bits are set to 0b0. After this stage the valid temperature is written automatically by each FSM in the CONTROL_TEMP_SENSOR_MPU[9:0] BGAP_DTEMP_MPU, CONTROL_TEMP_SENSOR_MM[9:0] BGAP_DTEMP_MM, and CONTROL_TEMP_SENSOR_CORE[9:0] BGAP_DTEMP_CORE bit fields, and then software is able to read the valid temperature value from each register. After writing the valid temperature values the three FSMs wait one clock cycle and start another conversion cycle.

NOTE: The main delay between two measurements is controlled by the CONTROL_BANDGAP_MASK[29:28] COUNTER_DELAY bit field. After this delay there is an additional 5µs delay before a new temperature conversion starts. This is managed automatically by each FSM.

Figure 18-12 shows the timing sequence for a programmable-delay continuous conversion mode. The continuous temperature measurement is performed as a sequence of single ADC conversions automatically initiated at regular time intervals. As show in Figure 18-12, the duration of a single temperature conversion is 17 bandgap clock cycles regardless of the CLK frequency.

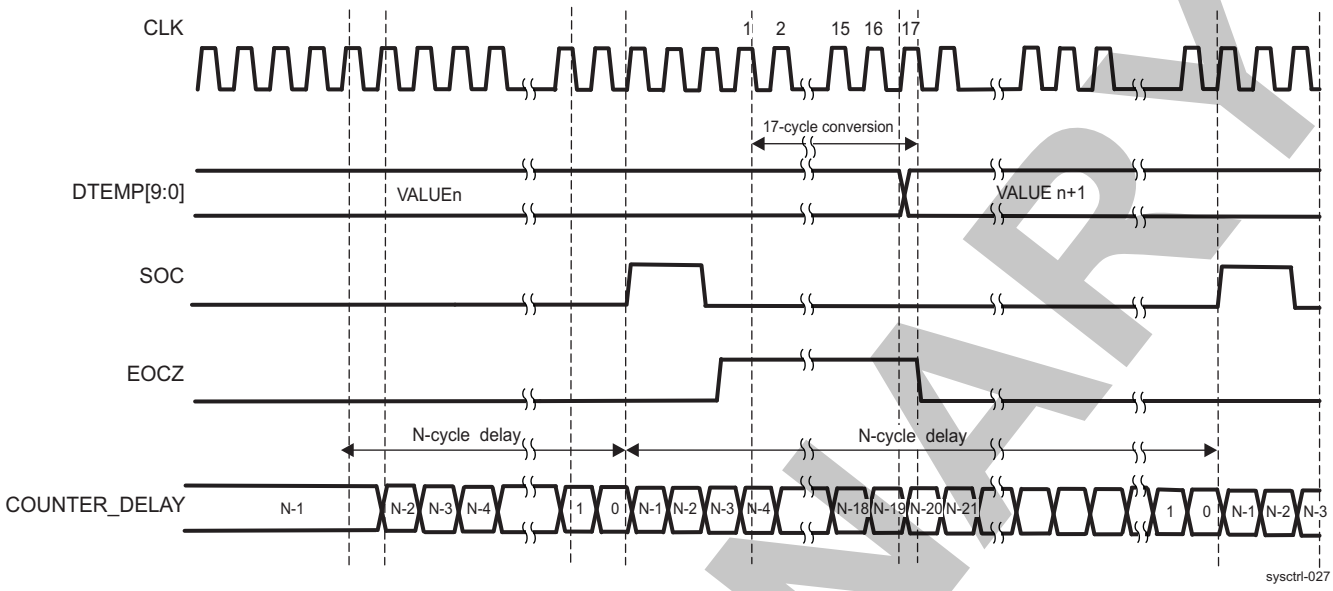
Figure 18-12. Programmable-Delay Continuous Conversion Mode



18.4.10.2.2 Thermal Data Post-Processing Logic

A thermal data post-processing logic with dedicated registers is implemented in the general core control module. The registered ADC value from each of the three temperature sensors is passed in parallel to the inputs of four comparators (two blocks of two comparators). In each block, the temperature data is compared to high- and low-temperature thresholds, to handle the hysteresis effect when temperature decreases. Three sets of two comparator blocks provide different thermal management functions.

Figure 18-13 shows the thermal management schema in the device.

There are three register sets

- CONTROL_TEMP_SENSOR_MPU, CONTROL_BANDGAP_TSHUT_MPU, CONTROL_BANDGAP_THRESHOLD_MPU, CONTROL_BANDGAP_CUMUL_DTEMP_MPU, and CONTROL_DTEMP_MPU_x (where x = 0 to 4) for the MPU thermal sensor
- CONTROL_TEMP_SENSOR_MM, CONTROL_BANDGAP_TSHUT_MM, CONTROL_BANDGAP_THRESHOLD_MM, CONTROL_BANDGAP_CUMUL_DTEMP_MM, and CONTROL_DTEMP_MM_x (where x = 0 to 4) for the GPU thermal sensor
- CONTROL_TEMP_SENSOR_CORE, CONTROL_BANDGAP_TSHUT_CORE, CONTROL_BANDGAP_THRESHOLD_CORE, CONTROL_BANDGAP_CUMUL_DTEMP_CORE, and CONTROL_DTEMP_CORE_x (where x = 0 to 4) for the device die center thermal sensor.

For more information, see Table 18-63 *Temperature Sensor Registers*.

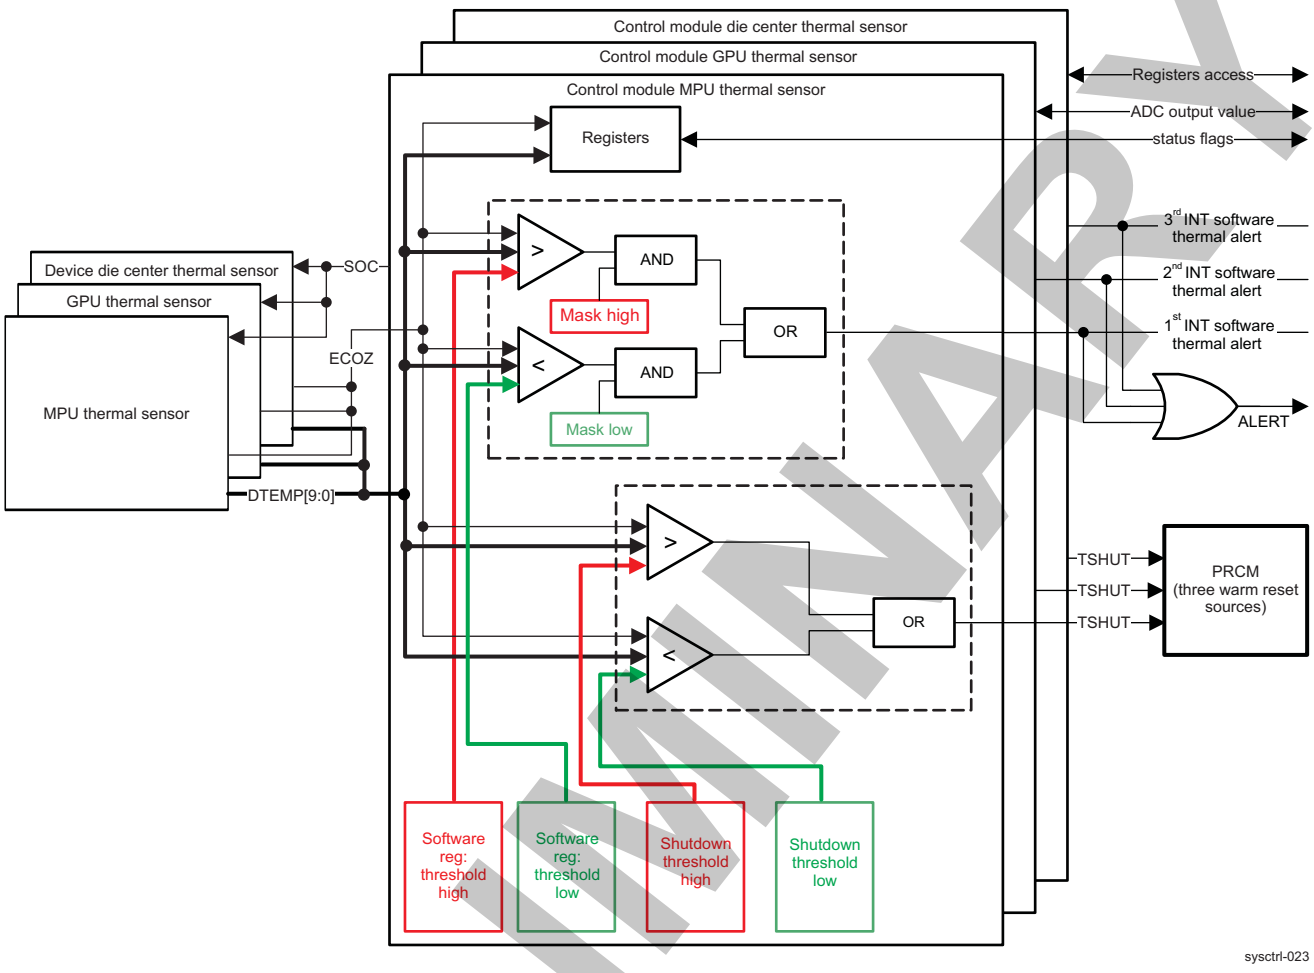
Figure 18-13. Thermal Management Schema



18.4.10.2.3 Thermal Alert Functionality Comparators

There are three sets (for MPU, for GPU, and for the device die center) of two comparator blocks inside the general core control module. The first three comparator blocks are programmable and provide a thermal alert function output. The high-temperature threshold for this function is configurable through the follwoing 10-bit fields:

- CONTROL_BANDGAP_THRESHOLD_MPU[25:16] THOLD_HOT_MPU for the MPU temperature sensor
- CONTROL_BANDGAP_THRESHOLD_MM[25:16] THOLD_HOT_MM for the GPU temperature sensor
- CONTROL_BANDGAP_THRESHOLD_CORE[25:16] THOLD_HOT_CORE for the device die center temperature sensor

The low-temperature threshold for this function is configurable through the following 10-bit fields:

- CONTROL_BANDGAP_THRESHOLD_MPU[9:0] THOLD_COLD_MPU for the MPU temperature sensor
- CONTROL_BANDGAP_THRESHOLD_MM[9:0] THOLD_COLD_MM for the GPU temperature sensor
- CONTROL_BANDGAP_THRESHOLD_CORE[9:0] THOLD_COLD_CORE for the device die center temperature sensor

Thermal alert logic in the general core control module provides the capability to mask (active low) comparator outputs for hot events through the CONTROL_BANDGAP_MASK[1] MASK_HOT_MPU, CONTROL_BANDGAP_MASK[3] MASK_HOT_MM and CONTROL_BANDGAP_MASK[5] MASK_HOT_CORE bits, and for cold events through the CONTROL_BANDGAP_MASK[0] MASK_COLD_MPU, CONTROL_BANDGAP_MASK[2] MASK_COLD_MM, and CONTROL_BANDGAP_MASK[4] MASK_COLD_CORE bits. The masked HOT and COLD point-monitoring signals from each of the three comparator blocks are ORed in three thermal alert signals (first, second, third INT software thermal alert) (for details, see Figure 18-13). These three signals are then ORed in the THERMAL_ALERT signal, which delivers an interrupt to the MPU subsystem on the MPU_IRQ_126 input (see Section 18.3, *Control Module Integration*). Software can use this interrupt to implement the thermal management policy of the device. For more information about this interrupt, see Section 17.3.2, *Interrupt Requests to INTC_MPU*, in Chapter 17, *Interrupt Controllers*.

The nonmasked outputs of the thermal alert logic comparators are individually registered in the following read-only (RO) bits:

- CONTROL_BANDGAP_STATUS[1] HOT_MPU
- CONTROL_BANDGAP_STATUS[3] HOT_MM
- CONTROL_BANDGAP_STATUS[5] HOT_CORE
- CONTROL_BANDGAP_STATUS[0] COLD_MPU
- CONTROL_BANDGAP_STATUS[2] COLD_MM
- CONTROL_BANDGAP_STATUS[4] COLD_CORE

The THERMAL_ALERT signal is mapped to the CONTROL_BANDGAP_STATUS[31] ALERT RO bit.

Figure 18-14 shows the behavior of the thermal alert logic.

18.4.10.2.4 Thermal Shutdown Functionality Comparators

There are three sets (for MPU, for GPU, and for the device die center) of two comparator blocks inside the general core control module. The second set of three comparator blocks cannot be programmed and are responsible for the thermal shutdown protection of the device. The values of the three high and low TSHUT thresholds are set by default and connot be overriden by software.

High thresholds can be read through the following bit fields:

- CONTROL_BANDGAP_TSHUT_MPU[25:16] TSHUT_HOT_MPU
- CONTROL_BANDGAP_TSHUT_MM[25:16] TSHUT_HOT_MM
- CONTROL_BANDGAP_TSHUT_CORE[25:16] TSHUT_HOT_CORE

Low thresholds can be read through the following bit fields:

- CONTROL_BANDGAP_TSHUT_MPU[9:0] TSHUT_COLD_MPU
- CONTROL_BANDGAP_TSHUT_MM[9:0] TSHUT_COLD_MM
- CONTROL_BANDGAP_TSHUT_CORE[9:0] TSHUT_COLD_CORE

When the maximum allowed MPU, GPU, or device die center temperature is reached, one of the three TSHUT outputs is activated, respectively (see Figure 18-13). Each of these TSHUT outputs is tied internally to the PRCM module, and is used as a warm reset signal. It flags that the maximum MPU, GPU, or device die center junction temperature is reached.

To deactivate each TSHUT output, the temperature must go below the value of each low TSHUT threshold.

Figure 18-15 shows the behavior of the TSHUT logic.

18.4.10.2.5 Temperature Timestamping

Each time one of the three bit fields (CONTROL_TEMP_SENSOR_MPU[9:0] BGAP_DTEMP_MPU, CONTROL_TEMP_SENSOR_MM[9:0] BGAP_DTEMP_MM, and CONTROL_TEMP_SENSOR_CORE[9:0] BGAP_DTEMP_CORE) is updated with new temperature value, this value is also automatically stored into a 5-level deep FIFO and a timestamp is also registered. The FIFO registers are in CTRL_MODULE_CORE.

There are three (one for MPU, one for GPU, and one for the device die center) 5-level FIFOs which store a brief history for the last few temperature measurements and are also dedicated to temperature timestamping feature.

The MPU FIFO consists of the following registers:

- CONTROL_DTEMP_MPU_0
- CONTROL_DTEMP_MPU_1
- CONTROL_DTEMP_MPU_2
- CONTROL_DTEMP_MPU_3
- CONTROL_DTEMP_MPU_4

The GPU FIFO consists of the following registers:

- CONTROL_DTEMP_MM_0
- CONTROL_DTEMP_MM_1
- CONTROL_DTEMP_MM_2
- CONTROL_DTEMP_MM_3
- CONTROL_DTEMP_MM_4

The device die center FIFO consists of the following registers:

- CONTROL_DTEMP_CORE_0
- CONTROL_DTEMP_CORE_1
- CONTROL_DTEMP_CORE_2
- CONTROL_DTEMP_CORE_3
- CONTROL_DTEMP_CORE_4

Table 18-18 shows a generic description of FIFOs.

Each FIFO has two fields. The first one is 10 bits wide, 5 levels deep, and is intended to store the temperature values for the last five measurements. The second field is 22 bits wide, 5 levels deep, and acts like a counter for the number of temperature measurements.

Table 18-18. FIFOs Generic Description

FIFO Levels	Second FIFO Field (22 Bits) – Timestamp Bits [31:10] (x=MPU,MM and CORE)	Description	First FIFO field (10 Bits) – Temperature Bits [9:0] (x=MPU,MM and CORE)	Description
Level 1	DTEMP_TAG_x_0	Indicates the number of temperature measurements	DTEMP_TEMPERATURE_x_0	Indicates the last measured temperature value (the most recent sample)
Level 2	DTEMP_TAG_x_1	Indicates the number of temperature measurements minus one (DTEMP_TEMPERATURE_x_0 – 1)	DTEMP_TEMPERATURE_x_1	Indicates the penultimate measured temperature value
Level 3	DTEMP_TAG_x_2	Indicates the number of temperature measurements minus two (DTEMP_TEMPERATURE_x_0 – 2)	DTEMP_TEMPERATURE_x_2	Indicates temperature value measured before DTEMP_TEMPERATURE_x_1

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 18-18. FIFOs Generic Description (continued)

FIFO Levels	Second FIFO Field (22 Bits) – Timestamp Bits [31:10] (x=MPU,MM and CORE)	Description	First FIFO field (10 Bits) – Temperature Bits [9:0] (x=MPU,MM and CORE)	Description
Level 4	DTEMP_TAG_x_3	Indicates the number of temperature measurements minus three (DTEMP_TEMPERATURE_x_0 – 3)	DTEMP_TEMPERATURE_x_3	Indicates temperature value measured before DTEMP_TEMPERATURE_x_2
Level 5	DTEMP_TAG_x_4	Indicates the number of temperature measurements minus four (DTEMP_TEMPERATURE_x_0 – 4)	DTEMP_TEMPERATURE_x_4	Indicates temperature value measured before DTEMP_TEMPERATURE_x_3 (the oldest sample)

NOTE: DTEMP_TAG_x_4 (where x=MPU,MM and CORE) increments its value with one after each fifth temperature measurement.

DTEMP_TAG_x_3 (where x=MPU,MM and CORE) increments its value with one after each forth temperature measurement.

DTEMP_TAG_x_2 (where x=MPU,MM and CORE) increments its value with one after each third temperature measurement.

DTEMP_TAG_x_1 (where x=MPU,MM and CORE) increments its value with one after each second temperature measurement.

DTEMP_TAG_x_0 (where x=MPU,MM and CORE) increments its value with one after each temperature measurement.

Software can stop a certain FIFO to update with new temperature and timestamp values when setting one of the following bits to 0x1:

- CONTROL_BANDGAP_MASK[21] FREEZE_MPU for the MPU FIFO.
- CONTROL_BANDGAP_MASK[22] FREEZE_MM for the GPU FIFO.
- CONTROL_BANDGAP_MASK[23] FREEZE_CORE for the device die center FIFO.

These 3 bits are automatically cleared by hardware after FIFOs are reset.

Each FIFO can also be cleared setting the following bits to 0x1:

- CONTROL_BANDGAP_MASK[18] CLEAR_MPU for the MPU FIFO.
- CONTROL_BANDGAP_MASK[19] CLEAR_MM for the GPU FIFO.
- CONTROL_BANDGAP_MASK[20] CLEAR_CORE for the device die center FIFO.

These 3 bits are automatically cleared by hardware after FIFOs are reset.

18.4.10.2.6 Temperature Accumulators

Three registers are intended to accumulate the temperature after each measurement. The value of every next temperature measurement is added to the previous value and then stored in the following bit fields:

- CONTROL_BANDGAP_CUMUL_DTEMP_MPU[31:0] CUMUL_DTEMP_MPU
- CONTROL_BANDGAP_CUMUL_DTEMP_MM[31:0] CUMUL_DTEMP_MM
- CONTROL_BANDGAP_CUMUL_DTEMP_CORE[31:0] CUMUL_DTEMP_CORE

Software can divide the accumulated in each register value to the number of measurements and thus get the average temperature. For example, the MPU average temperature for a given time period is:

MPU Average Temperature = CONTROL_BANDGAP_CUMUL_DTEMP_MPU[31:0] CUMUL_DTEMP_MPU / CONTROL_DTEMP_MPU_0[31:10] DTEMP_TAG_MPU_0

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

Software can reset CONTROL_BANDGAP_CUMUL_DTEMP_MPU[31:0] CUMUL_DTEMP_MPU, CONTROL_BANDGAP_CUMUL_DTEMP_MM[31:0] CUMUL_DTEMP_MM, and CONTROL_BANDGAP_CUMUL_DTEMP_CORE[31:0] CUMUL_DTEMP_CORE temperature accumulators through bits CONTROL_BANDGAP_MASK[15] CLEAR_ACCUM_MPU, CONTROL_BANDGAP_MASK[16] CLEAR_ACCUM_MM, and CONTROL_BANDGAP_MASK[17] CLEAR_ACCUM_CORE, respectively, setting each one of them to 0x1. These bits also reset the three FIFOs and are automatically cleared by hardware when the reset procedure completes.

18.4.10.2.7 Bandgap FSMs Power Management

Each one of the three bandgap FSMs comply with the PRCM power-management protocol. They share common functional clock (L3INSTR_TS_GCLK), which is automatically gated by PRCM depending on the value of the CONTROL_BANDGAP_MASK[31:30] SIDLEMODE bit field. L3INSTR_TS_GCLK clock is also enabled automatically by the PRCM module.

18.4.10.2.8 ADC Codes Versus Temperature

Table 18-19 gives the temperature range that corresponds to each value of the following bit fields:

- CONTROL_TEMP_SENSOR_MPU[9:0] BGAP_DTEMP_MPU
- CONTROL_TEMP_SENSOR_MM[9:0] BGAP_DTEMP_MM
- CONTROL_TEMP_SENSOR_CORE[9:0] BGAP_DTEMP_CORE

18.4.11 Hardware Observability

18.4.11.1 Device Internal Signals Observability Overview

The general control module provides observability features covering different module internal signals related to:

- Power and reset management protocol inside different power domains
- Power domain states and transition indication

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- IRQs by different modules
- DMA requests by different modules
- Clocks and clock management

The associated signal multiplexing function is controlled through the hardware observability I/O multiplexing registers (32-bit read/write registers). The selected observable signals reside in the CORE or WKUP power domain and are mapped on the po_hw_dbg[31:0] observability bus, which is in the WKUP power domain. The po_hw_dbg[31:16] and po_hw_dbg[15:0] observability outputs are then further multiplexed as their corresponding hw_dbg[31:16] and hw_wkdbg[15:0] signals on the different pads of the CORE and WKUP power domain, respectively.

Figure 18-16 is an overview of observability multiplexing, which minimizes the number of signals exchanged at the device boundary.

18.4.11.2 Observability Gating Capabilities

The programmer has the option to gate all 32 signals of the observability bus simultaneously at the observability paths of the CORE and WKUP power domains, keeping them tied to 1 (CONTROL_HWOBS_CONTROL[1] HWOBS_ALL_ONE_MODE = 0b1) or keeping them tied to 0 (CONTROL_HWOBS_CONTROL[2] HWOBS_ALL_ZERO_MODE = 0b1). This can be useful to check the path from hardware observability to external pads. These 2 bits must be set to 0 to enable the observability feature for all observability pads.

Additionally, the CONTROL_HWOBS_CONTROL[0] HWOBS_MACRO_ENABLE bit provides the gating feature only to observability signals muxed in the CORE power domain that come from the following modules (identified in the so-called MACRO group):

- MPU subsystem
- DSP subsystem
- IVA
- Display subsystem
- CM_CORE
- ABE

When the CONTROL_HWOBS_CONTROL[0] HWOBS_MACRO_ENABLE bit is set to 0b0, the observability outputs associated with the MACRO group are gated and forced to 0b0.

NOTE: Do not set the observability gating bits CONTROL_HWOBS_CONTROL[1] HWOBS_ALL_ONE_MODE and CONTROL_HWOBS_CONTROL[2] HWOBS_ALL_ZERO_MODE simultaneously to 1 to avoid undefined states of the observability bus.

In the CORE power domain, the frequency of the signals which are mapped on po_hw_dbg[2:0] lines can be optionally divided by 1, 2, 4, 8, or 16 through programming dedicated bit fields in the CONTROL_HWOBS_CONTROL register.

Assignment of the dividers is as follows:

- CONTROL_HWOBS_CONTROL[7:3] HWOBS_CLKDIV_SEL for po_hw_dbg0
- CONTROL_HWOBS_CONTROL[13:9] HWOBS_CLKDIV_SEL_1 for po_hw_dbg1
- CONTROL_HWOBS_CONTROL[18:14] HWOBS_CLKDIV_SEL_2 for po_hw_dbg2

NOTE: To enable observability over the po_hw_dbg0, po_hw_dbg1, and po_hw_dbg2 bus lines, the respective bit fields in the CONTROL_HWOBS_CONTROL register (HWOBS_CLKDIV_SEL, HWOBS_CLKDIV_SEL_1, and HWOBS_CLKDIV_SEL_2) must be set different than 0. The default value (0) is not sufficient to see an observability value.

NOTE: The frequency division and ability to gate the MACRO group observability signals (configurable in the CONTROL_HWOBS_CONTROL register) are limited only to hardware observability signals multiplexed and propagated in the CORE power domain (CONTROL_DEBOBS_FINAL_MUX_SEL[i] SELECT = 0b1).

These options do not apply to hardware observability signals muxed and propagated in the WKUP power domain (CONTROL_DEBOBS_FINAL_MUX_SEL[i] SELECT = 0b0).

18.4.11.3 Observability Signals Multiplexing at General Core/Wake-Up Control Level

Most of the observability multiplexers (MACRO group modules/DPLLs/sDMA associated) are configurable in CTRL_MODULE_CORE, which is part of the switchable CORE power domain. Signal multiplexers are also instantiated in CTRL_MODULE_WKUP (CM1/PRM/ABE dedicated), which is part of the WKUP power domain. The CONTROL_DEBOBS_FINAL_MUX_SEL[31:0] SELECT bit field, instantiated in the CORE power domain, selects a signal to be observed between the outputs at the CORE and WKUP multiplexing levels. A bit from this register set to 1 selects to route a signal from the CORE power domain to a certain po_hw_dbgn (where n = 0 to 31) line; when the bit is set to 0, selects to route a signal from the WKUP power domain to the same line. The output of this top-level multiplexing is further passed to the pad configuration muxing I/O level within device control module boundaries.

The module and view-channel selection/reduction layer in the CORE domain is configured through the 5-bit field MODE in the 32 × 32-bit registers CONTROL_CORE_CONF_DEBUG_SEL_TST_0 through CONTROL_CORE_CONF_DEBUG_SEL_TST_31. The following modules can be selected as source of observability signals: Cortex-A15 MPU subsystem, DSP subsystem, IVA, display subsystem, CM2, and ABE (MACRO signal sources).

Some of the CONTROL_CONF_DEBUG_SEL_TST registers are responsible for selection of sDMA view channels, different DPLL clock view channels, and other signal view channels.

- 3 x DPLL clkout signal view channels
- 7 x DPLL (other than clkout signal) view channels
- 5 x sDMA signal view channels
- 3 x additional clkout view channels monitoring the hwobs_coredivider_clkout3, hwobs_perdivider_clkout4, and hwobs_pd_l4_per_per32k_gfclk signals

Table 18-20 summarizes the internal signals multiplexing schema for each of the 32 CONTROL_CORE_CONF_DEBUG_SEL_TST registers.

  - DSI1_A DPLL
  - DSI1_C DPLL
  - USB DPLL
  - HDMI DPLL
  - SATA DPLL
  - USBOTGSS DPLL
- The register bit fields associated with the seven different DPLL signal view channels are summarized in Table 18-21. Again, the 4-bit MULT bit field in each of the seven registers makes it possible to choose the source of the DPLL signal to be one of the following DPLLs in the device:
  - CORE DPLL
  - ABE DPLL
  - PER DPLL
  - DSI1_A DPLL
  - DSI1_C DPLL
  - USB DPLL
  - HDMI DPLL
  - SATA DPLL
  - USBOTGSS DPLL
- Nine registers are associated with the power-management observable signals of MMCx (where x = 1 to 5) modules. These registers are summarized in Table 18-22.
- There are four independent sDMA request view channels, each of which has a dedicated register (CONTROL_CONF_SDMA_REQ_SEL0 through CONTROL_CONF_SDMA_REQ_SEL3) with a 7-bit MULT bit field to select 1 from 127 possible DMA_SYSTEM request signals for observation purposes. For more information, see Section 16.1, *DMA_SYSTEM Module Overview*. The fifth channel, sdma_req_view_all, is acquired by applying logical AND reduction over the four currently selected sDMA view channel output signals.
- The General Core observability logic input (hwobs_pd_l4_per_per32k_gfclk) is tied to a PRM output observability signal. This PRM signal corresponds to the hardware gated in the CD_L4_PER clock domain clock (PER_32K_GFCLK), which is directly sourced by the SCRM clock (SYS_32K).
- The General Core observability logic input, hwobs_coredivider_clkout3, is tied to the Core DPLL observability output, CLK_FUNC_1_0_3, which is a direct (nongated, nondivided) version of the CORE DPLL clock output, CLKOUTX2_M3.
- The General Core observability logic input, hwobs_perdivider_clkout4, is tied to the Core DPLL observability output, CLK_FUNC_1_0_4, which is a direct (nongated, nondivided) version of the PER DPLL clock output, CLKOUTX2_M4. For more information, see Section 3.6.3.4, *DPLL_PER Description*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 18-21 lists the DPLL signal observability controls.

Table 18-21. DPLL Signal Observability Controls

Feature	Type	Register/Bit Field/Observability Control	Description
Different domain DPLL freqlock observability	Control	CONTROL_CONF_DPLL_FREQLOCK_SEL[3:0] MULT	Selects DPLL freqlock view channel
Different domain DPLL phaselock observability	Control	CONTROL_CONF_DPLL_PHASELOCK_SEL[3:0] MULT	Selects DPLL phaselock view channel
Different domain DPLL tinitz observability	Control	CONTROL_CONF_DPLL_TINITZ_SEL[3:0] MULT	Selects to observe DPLL tinitzview channel
Different domain DPLL tenable observability	Control	CONTROL_CONF_DPLL_TENABLE_SEL[3:0] MULT	Selects to observe DPLL tenableview channel
Different domain DPLL tenablediv observability	Control	CONTROL_CONF_DPLL_TENABLEDIV_SEL[3:0] MULT	Selects to observe DPLL tenabledivview channel
Different domain DPLL bypassack observability	Control	CONTROL_CONF_DPLL_BYPASSACK_SEL[3:0] MULT	Selects to observe DPLL bypassackview channel
Different domain DPLL idle observability	Control	CONTROL_CONF_DPLL_IDLE_SEL[3:0] MULT	Selects to observe DPLL idleview channel

Table 18-22. MMCx Signal Observability Controls

Register/Bit Field/Observability Control	Description
CONTROL_CONF_MMCX_ADPIDLE_SEL[2:0] MULT	Selects to observe hwobs_mmcx_adpidle (where x = 1 to 5)
CONTROL_CONF_MMCX_ADPDAT1PADEN_SEL[2:0] MULT	Selects to observe hwobs_mmcx_adpdat1paden (where x = 1 to 5)
CONTROL_CONF_MMCX_OCPL4IDLEREQ_SEL[2:0] MULT	Selects to observe hwobs_mmcx_ocpl4idlereq (where x = 1 to 5)
CONTROL_CONF_MMCX_OCPL3MWAIT_SEL[2:0] MULT	Selects to observe hwobs_mmcx_ocpl3mwait (where x = 1 to 5)
CONTROL_CONF_MMCX_PIRFFRET_SEL[2:0] MULT	Selects to observe hwobs_mmcx_pirffret (where x = 1 to 5)
CONTROL_CONF_MMCX_OCPL4SIDLEACKO1_SEL[2:0] MULT	Selects to observe hwobs_mmcx_ocpl4sidleacko_1 (where x = 1 to 5)
CONTROL_CONF_MMCX_OCPL4SIDLEACKO0_SEL[2:0] MULT	Selects to observe hwobs_mmcx_ocpl4sidleacko_0 (where x = 1 to 5)
CONTROL_CONF_MMCX_OCPL3MSTANDBYO_SEL[2:0] MULT	Selects to observe hwobs_mmcx_ocpl3mstandbyo (where x = 1 to 5)
CONTROL_CONF_MMCX_SWAKEUP_SEL[2:0] MULT	Selects to observe hwobs_mmcx_swakeup (where x = 1 to 5)

PRELIMINARY

NOTE: Features configured in the following registers are limited to hardware observability signals multiplexed and propagated in the CORE power domain (CONTROL_DEBOBS_FINAL_MUX_SEL[i] SELECT = 0b1):

- CONTROL_CORE_CONF_DEBUG_SEL_TST_0 through CONTROL_CORE_CONF_DEBUG_SEL_TST_31
- CONTROL_CONF_CLK_SEL0[3:0] MULT through CONTROL_CONF_CLK_SEL2[3:0] MULT
- CONTROL_CONF_SDMA_REQ_SEL0 through CONTROL_CONF_SDMA_REQ_SEL3
- CONTROL_CONF_MMCX_ADPIDLE_SEL through CONTROL_CONF_MMCX_SWAKEUP_SEL
- CONTROL_CONF_DPLL_FREQLOCK_SEL
- CONTROL_CONF_DPLL_TINITZ_SEL
- CONTROL_CONF_DPLL_PHASELOCK_SEL
- CONTROL_CONF_DPLL_TENABLE_SEL
- CONTROL_CONF_DPLL_TENABLEDIV_SEL
- CONTROL_CONF_DPLL_BYPASSACK_SEL
- CONTROL_CONF_DPLL_IDLE_SEL

These options do not apply to hardware observability signals muxed and propagated in the WKUP power domain (CONTROL_DEBOBS_FINAL_MUX_SEL[i] SELECT = 0b0).

The CONTROL_WKUP_CONF_DEBUG_SEL_TST_i[1:0] MODE bit (where i = 0 to 31) provides the option to choose between observation of power and reset manager signals in the device or observation of signals related to CM1. If CONTROL_WKUP_CONF_DEBUG_SEL_TST_i[1:0] = 0b1, the hwobs_int_prm_i signal is selected. Otherwise, the hwobs_int_cm1_i signal is output.

NOTE: The CM1 and PRM observable signals are multiplexed in the WKUP power domain.

18.4.11.4 Observability Signals Multiplexing at Device Control Module Level

The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw_dbgn/hw_wkdbgn) of the pad.

18.4.11.4.1 Observability Signals Muxed on Pads in the CORE Power Domain

To map the hw_dbg16 through hw_dbg31 signals to their associated external device pads in the CORE power domain, set the related MUXMODE bit fields within the CONTROL_CORE_PAD0_C2C_DATAOUT0_PAD1_C2C_DATAOUT1 through CONTROL_CORE_PAD0_C2C_DATA14_PAD1_C2C_DATA15 pad configuration registers to 0b101 (mode 5). These signals can also be mapped on the external device pads in the CORE power domain through the following registers (MUXMODE = 0x5):

- CONTROL_CORE_PAD0_UART2_RTS_PAD1_UART2_CTS through CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX to map hw_dbg16 through hw_dbg19 signals on the uart2_rts – uart2_tx pads, respectively
- CONTROL_CORE_PAD0_MCSPI2_CLK_PAD1_MCSPI2_SIMO[31:16] to map the hw_dbg20 signal on the mcspi2_simo pad
- CONTROL_CORE_PAD0_MCSPI2_SOMI_PAD1_MCSPI2_CS0[15:0] to map the hw_dbg21 signal on the mcspi2_somi pad
- CONTROL_CORE_PAD0_GPIO6_184_PAD1_GPIO6_185 through CONTROL_CORE_PAD0_GPIO6_186_PAD1_GPIO6_187 to map hw_dbg22 through hw_dbg25 signals on the gpio6_184 – gpio6_187 pads, respectively
- CONTROL_CORE_PAD0_CAM_GLOBALRESET_PAD1_TIMER11_PWM_EVT[31:16] to map the hw_dbg26 signal on the timer11_pwm_evt pad
- CONTROL_CORE_PAD0_TIMER8_PWM_EVT_PAD1_I2C3_SCL to map the hw_dbg27signal on the timer8_pwm_evt pad

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- CONTROL_CORE_PAD0_UART5_RX_PAD1_UART5_TX through CONTROL_CORE_PAD0_UART5_CTS_PAD1_UART5_RTS to map hw_dbg28 through hw_dbg31 signals on the uart5_rx – uart5_rts pads, respectively

For more information, see Table 18-9.

18.4.11.4.2 Observability Signals Muxed on Pads in the WKUP Power Domain

To map the hw_wkdbg0 through hw_wkdbg15 signals to their associated external device pads in the WKUP power domain, set the MUXMODE bit field to 0x5 in the following CTRL_MODULE_WKUP_PAD registers:

- CONTROL_WKUP_PAD0_LLIA_WAKEREQIN_PAD1_LLIB_WAKEREQIN to map the hw_wkdbg14 and hw_wkdbg13 signals on the llia_wakereqin and llib_wakereqin pads, respectively.
- CONTROL_WKUP_PAD0_DRM_EMU0_PAD1_DRM_EMU1 to map the hw_wkdbg6 and hw_wkdbg7 signals on the drm_emu0 and drm_emu1 pads, respectively.
- CONTROL_WKUP_PAD0_FREF_CLK0_OUT_PAD1_FREF_CLK1_OUT to map the hw_wkdbg9 and hw_wkdbg5 signals on the fref_clk0_out and fref_clk1_out pads, respectively.
- CONTROL_WKUP_PAD0_FREF_CLK2_OUT_PAD1_FREF_CLK2_REQ to map the hw_wkdbg10 and hw_wkdbg11 signals on the fref_clk2_out and fref_clk2_req pads, respectively.
- CONTROL_WKUP_PAD0_FREF_CLK1_REQ_PAD1_SYS_NRESPWRON[15:0] to map the hw_wkdbg12 signal on the fref_clk1_req pad.
- CONTROL_WKUP_PAD0_SYS_NRESWARM_PAD1_SYS_PWR_REQ[31:16] to map the hw_wkdbg15 signal on the sys_pwr_req pad.
- CONTROL_WKUP_PAD0_SYS_BOOT0_PAD1_SYS_BOOT1 through CONTROL_WKUP_PAD0_SYS_BOOT4_PAD1_SYS_BOOT5 to map the hw_wkdbg0 – hw_wkdbg4 and hw_wkdbg8 signals on the sys_boot0 – sys_boot5 pads, respectively.

For more information, see Table 18-8.

18.4.11.5 Observability Signals Sourced at Module Level

Observable signals coming from within different device subsystems are mapped to general core control and general wakeup control observability inputs. Additional multiplexing is also implemented inside some of the observable modules (see Figure 18-16).

18.4.11.5.1 MPU Subsystem Observable Signals

Table 18-23 through Table 18-38 list the MPU subsystem observable signals available in 16 functional multiplexing modes. The mode is selected at the general core control module level by programming the CONTROL_DEBOBS_MMR_MPU[3:0] SELECT bit field.

Table 18-23. Observability Signals Multiplexing at MPU Subsystem Level – Mode 0

18.4.11.5.2 IVA Subsystem Observable Signals

Table 18-39 lists the full set of 13 IVA observable signals from inside the IVA subsystem. No observability signal multiplexing is implemented at the IVA level. POHWDBGOUT[31:0] outputs are internal signals exported at IVA boundary to provide support during platform debug. They are enabled when PIHWDBGEN is high. They are always low when PIHWDBGEN is low

18.4.11.5.4 DSP Subsystem Observable Signals

Table 18-41 through Table 18-47 show DSP subsystem observable signals available in sixteen multiplexing modes. The mode is selected at the general control module level through writing in the bit field DSPSS_MMU_GPR[3:0] HWDEBUG_MUX.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The DSPSS.DSPSS_MMU_GPR register provides mux control for hardware observability signals exported at the DSPSS boundary to the general control module. Interrupts, DMA requests, and other events can be seen on the PO_HW_DBG_OUT bus. The DSPSS.DSPSS_MMU_GPR register provides mux controls for selecting the appropriate 32-bit value to be output on the PO_HW_DBG_OUT signal bus. The mux values and associated signals that can be observed on the PO_HW_DBG_OUT bus are described in Chapter 20, *Memory Management Units*. Setting the DSPSS.DSPSS_MMU_GPR[15] FORCE_IDLE_REQ bit initiates IDLE request/acknowledgment protocol with various blocks; the acknowledge information can be observed when HWDEBUG_MUX = 4'b1110.

All interrupts into DSPSS can be observed by setting the DSPSS.DSPSS_MMU_GPR[3:0] HWDEBUG_MUX bit field to 0x6, 0x7, 0x8, and 0x9. All interrupts to the INTC, which includes external and internal interrupts, can be seen by setting the HWDEBUG_MUX values to 0x2, 0x3, 0x4, and 0x5. DMA requests can be seen when the HWDEBUG_MUX values are set to 0xA and 0xB.

DPLL_IVA and the associated HSDIVIDER values can be seen by values of 0x0, the default reset value. DSPSS raw CD0 clock is sent out without any division. Other clocks are divided by 32.

The DSPSS.DSPSS_MMU_GPR[15] FORCE_IDLE_REQ bit must be used only for observability purposes, not in functional mode. When set, the FORCE_IDLE_REQ bit causes IDLE requests to be sent to various components inside the DSPSS, and idle acknowledgment is displayed when the value of the HWDEBUG_MUX[3:0] bit field is 4'b1110; the signals listed can then be checked to determine which component is not idle.

NOTE: Once this feature is used, FORCE_IDLE_REQ must be set to 0 before continuing the observability process.

18.4.11.6 Cross-bar

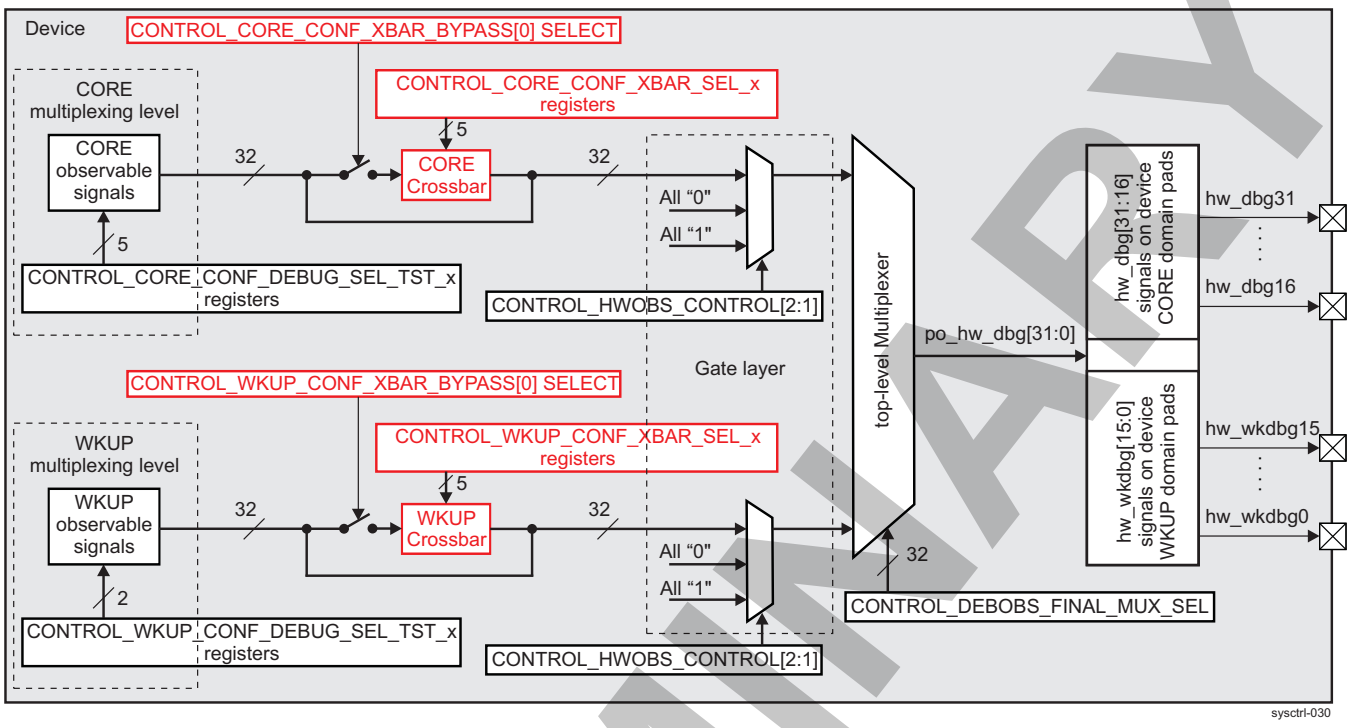
The cross-bar is part of the device observability logic. The purpose of the cross-bar is to shuffle any input observable signal to any output observable signal. There are two identical cross-bars, one for CORE observability signals and one for WKUP observability signals. Each cross-bar has 32 inputs and 32 outputs and can be seen as a 32-to-32 multiplexer. The cross-bar resides between the CORE/WKUP multiplexing level and the gate layer before the top-level multiplexer, which selects an observable signal between the CORE and WKUP power domains.

Figure 18-17 shows the location of the cross-bar in device observability logic.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 18-17. Cross-bar Location



The cross-bars in the CORE and in WKUP power domains can be bypassed by setting the CONTROL_CORE_CONF_XBAR_BYPASS[0] SELECT and CONTROL_WKUP_CONF_XBAR_BYPASS[0] SELECT bits to 0x1, respectively. By default both the cross-bars are bypassed.

Figure 18-18 represents the way in which the cross-bar works. The selection of an input signal to remap is made through the CONTROL_CORE_CONF_XBAR_SEL_x and CONTROL_WKUP_CONF_XBAR_SEL_x registers. Each of these registers has a structure described in Table 18-59. Each of the 5-bit fields (CONF_XBAR_SEL) selects one of the 32 observable input signals to be mapped on a certain cross-bar output. The number of each cross-bar output corresponds to the suffix number of each one of these 5-bit fields. For example:

- The CONTROL_CORE_CONF_XBAR_SEL_0[4:0] CONF_XBAR_SEL_0 bit field selects one of 32 observable signals to be mapped on cross-bar output 0.
- The CONTROL_CORE_CONF_XBAR_SEL_0[12:8] CONF_XBAR_SEL_1 bit field selects one of 32 observable signals to be mapped on cross-bar output 1.
- The CONTROL_CORE_CONF_XBAR_SEL_28[28:24] CONF_XBAR_SEL_31 bit field selects one of 32 observable signals to be mapped on cross-bar output 31.

The same logic is applied for cross-bar control registers in the WKUP power domain.

Table 18-60 shows all the cross-bar control registers.

18.4.12.2.1 CSI Receiver Control Register

To enable the physical layer of the camera receiver, the programmer manipulates the bits within the CONTROL_CAMERA_RX register as described in Table 18-64.

Table 18-64. CSI Receiver Control Register

Physical Address	Register Name	Description	Access
0x4A00 2E08	CONTROL_CAMERA_RX	Module dedicated configurations	RW

18.4.12.3 Protection Status Registers

Table 18-65 lists the protection status registers.

Table 18-65. Protection Status Registers

Physical Address	Register Name	Description	Access
0x4A00 2148	CONTROL_SEC_ERR_STATUS_FUNC	Protection firewall error status register	Public (R)
0x4A00 2150	CONTROL_SEC_ERR_STATUS_DEBUG	Protection firewall error status register debug	Public (RW)

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

These registers do not depend on the device type.

The CONTROL_SEC_ERR_STATUS_FUNC can be read in public mode, but cannot be written.

The CONTROL_SEC_ERR_STATUS_DEBUG register is both read and write accessible in GP devices.

These bits are cleared when the L3 and L4 firewall embedded-error log registers are cleared. All bits in these registers reflect internal events in the device related to the device protection.

On a specific event (signal rising edge), the corresponding bit is set. On a rising edge, the input signal must stay high for at least two interface clock periods to be recognized. Software must clear each bit after reviewing the events.

When a protection violation occurs, the following bits are set:

- In application mode:
  - CONTROL_SEC_ERR_STATUS_FUNC[1] = L3RAM protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[2] = GPMC protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[3] = EMIF protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[4] = IVA-HD protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[5] = Dual Cortex-M4 protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[6] = IVAHD SL2 protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[8] = SYSTEMDMA protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[10] = DISPDMA protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[13] = GPU protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[14] = DSS protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[15] = ISS protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[16] = L4_PER protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[17] = L4_CFG protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[18] = DebugSS protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[19] = AUDIOSS protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[22] = L4 wakeup protection violation

18.4.12.4 Protection SDRAM Configuration Registers

Table 18-66 lists the protection SDRAM configuration registers for EMIF1 and EMIF2 that are part of the general wakeup control module (CTRL_MODULE_WKUP). Upon POR, their values are exported as reset values of the EMIF1 and EMIF2 registers (EMIF_SDRAM_CONFIG and EMIF_SDRAM_CONFIG_2, respectively).

Table 18-66. Protection SDRAM Configuration Registers for EMIF1 and EMIF2

Physical Address	Register Name	Description	Access
0x4AE0 C110	CONTROL_PROT_EMIF1_SDRAM_CONFIG	Protection SDRAM configuration register 1. This register defines the bit field reset values of the EMIF1.EMIF_SDRAM_CONFIG register	RW
0x4AE0 C114	CONTROL_PROT_EMIF1_LPDDR2_NVM_CONFIG	Protection SDRAM configuration register 2. This register defines the bit field reset values of the EMIF1.EMIF_SDRAM_CONFIG_2 register	RW
0x4AE0 C118	CONTROL_PROT_EMIF2_SDRAM_CONFIG	Protection SDRAM configuration register 1. This register defines the bit field reset values of the EMIF2.EMIF_SDRAM_CONFIG register	RW
0x4AE0 C11C	CONTROL_PROT_EMIF2_LPDDR2_NVM_CONFIG2	Protection SDRAM configuration register 2. This register defines the bit field reset values of the EMIF2.EMIF_SDRAM_CONFIG_2 register	RW

18.4.12.5 Reference Voltage for Device LPDDR2/DDR3 I/O Buffers and LPDDR2/DDR3 Memory

The device LPDDR2/DDR3 I/O buffers work in so-called Vref-based receiver mode. In this mode, the buffers act like differential comparators with positive terminal connected to a device pad which receives signals from LPDDR2/DDR3 memory and negative terminal connected to a source of reference voltage. To work properly, a reference voltage must be provided to the device LPDDR2/DDR3 I/O buffers. Several Vref-generation cells are integrated in the device to supply this internal reference voltage. They are referred to as internal Vref-generation cells. There are also external Vref-generation cells which provide reference voltage to the externally connected LPDDR2/DDR3 memory.

Figure 18-19 shows the internal and external Vref-generation cells for the device.

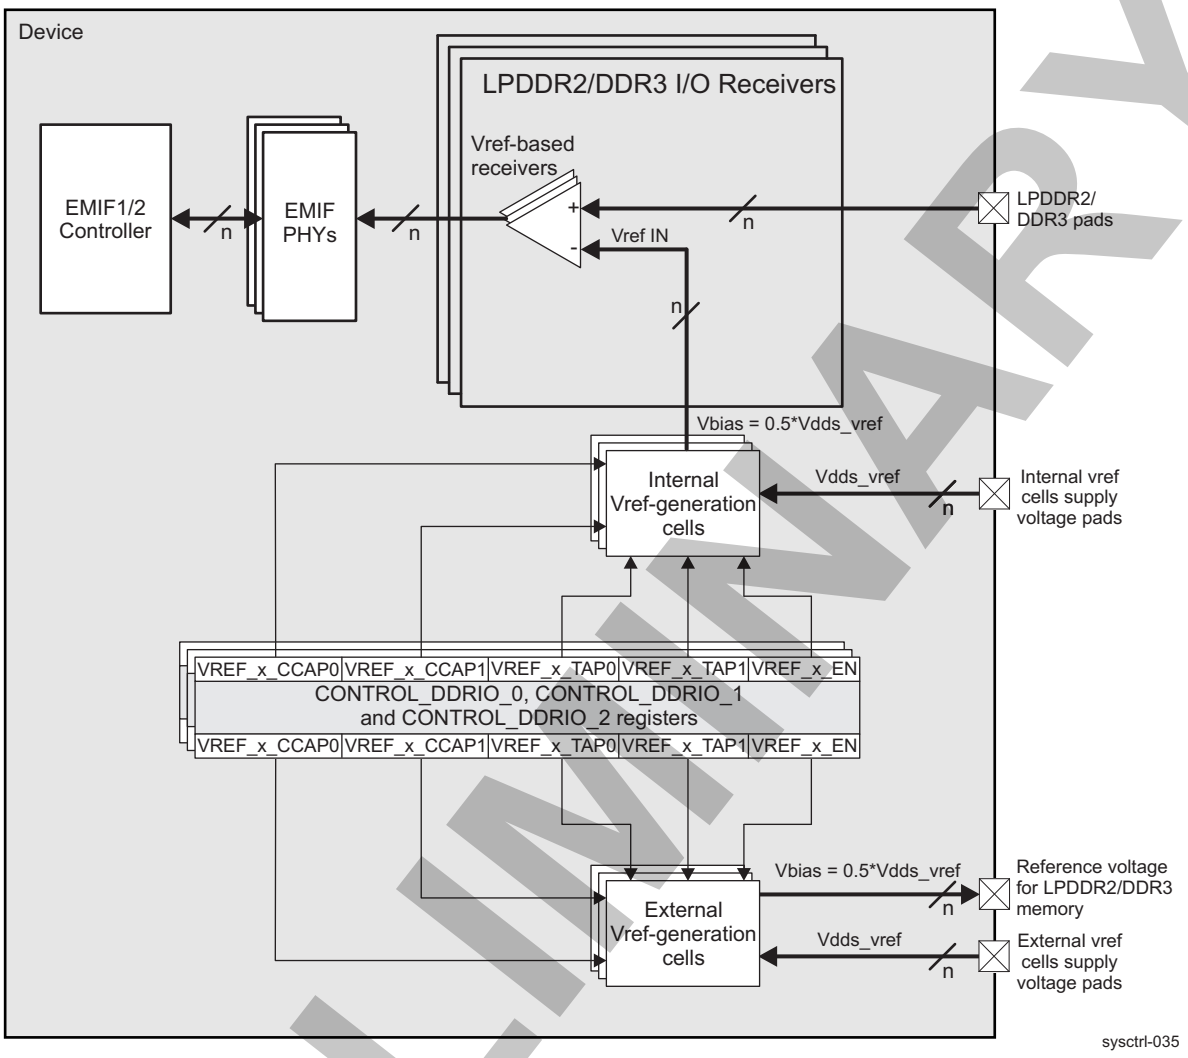
Figure 18-19. Internal and External Vref-Generation Cells and Their Controls



The Vref-generation cells reference voltage (Vbias) is equal to 0.5 × Vdds_vref, where Vdds_vref is the power supply voltage of the Vref cell. The Vref-based receiver allows improvement of speed performance when the LPDDR2/DDR3 I/Os are supplied by 1.2 V. A reference voltage is also provided to externally attached LPDDR2/DDR3 memory. The same type of Vref-generation cells are used for these external reference voltages.

The control bits for these internal and external Vref-generation cells reside in the CONTROL_DDRIO_0, CONTROL_DDRIO_1 and CONTROL_DDRIO_2 registers. Individual VREF_x_TAP[1:0] control bits set the output drive capability of the Vref cells. Table 18-67 lists the possible options for selection of load current sourced from the output of the Vref-generation cell.

Table 18-67. Vref Cell Load Current Selection

VREF_x_TAP1	VREF_x_TAP0	Description
0	0	2-µA load current
0	1	4-µA load current
1	0	8-µA load current
1	1	32-µA load current

According to the noise environment, the user can choose to filter the supplied reference voltage. Two coupling capacitors internal to the Vref-generation cell are available and configurable through the individual VREF_x_CCAP[1:0] control bits in the CONTROL_DDRIO_0, CONTROL_DDRIO_1 and CONTROL_DDRIO_2 registers, as specified in Table 18-68.

Table 18-68. Vref Cell Coupling Capacitor Selection

VREF_x_CCAP1	VREF_x_CCAP0	Capacitor
0	0	No capacitor connected.
0	1	One capacitor connected between Vbias and ground.(1)
1	0	One capacitor connected between Vbias and Vdds_vref.(2)
1	1	One capacitor connected between Vbias and ground and one capacitor connected between Vbias and Vdds_vref.

(1) Vbias is the output of the Vref-generation cell which provides the reference voltage.
(2) Vdds_vref is the power supply voltage of the Vref-generation cell.

The Vref-gereration cells can be enabled by setting the VREF_x_EN bits in the CONTROL_DDRIO_0, CONTROL_DDRIO_1, and CONTROL_DDRIO_2 registers to 0x1; these cells can be disabled (for leakage improvement and when not in use) by clearing the same VREF_x_EN bits.

There are the following internal and external Vref-generation cells per memory channel:

- Four internal Vref-generation cells providing reference voltage for the device LPDDR2/DDR3 DQ line I/Os (one Vref cell per data byte);
- One external Vref-generation cell that is intended to provide reference voltage to CA line receivers of the LPDDR2 memory;
- One external Vref-generation cell that provides reference voltage simultaneously to the four DQ lines of the LPDDR2/DDR3 memory;
- Two external Vref-generation cells intended to provide reference voltage to the command and address line receivers of the DDR3 memory.

NOTE: For leakage improvement software must set the CONTROL_DDRIO_2[27] LPDDR2CH1_VREF_CA_INT_EN and CONTROL_DDRIO_2[17] LPDDR2CH2_VREF_CA_INT_EN bits to 0x0.

Table 18-69 shows the internal Vref-generation cells control bits and the LPDDR2/DDR3 IOs pads used as receivers to which the corresponding Vref cell supplies reference voltage.

18.4.12.6 Force MPU Write Nonposted Transactions Control Register

At the top level, software can force all writes from the MPU subsystem to the L3 interconnect to be nonposted, regardless of the attributes of the transactions coming from the MPU. When active-high bit FORCEWRNP = 1, only nonposted write commands are sent to the L3 interconnect. This bit must remain stable for the entire transfer and must not change during the transfer.

Table 18-71 describes the general core control module register with FORCEWRNP control.

18.4.12.7 Signal Integrity Parameter Control Registers With Pad Group Assignment

18.4.12.7.1 Signal Integrity Parameter Controls Overview

Most of the I/O cells associated with the device pads can be configured to deliver their carried signals to the targeted input with maximum signal integrity. Configuration of these I/Os is done by pad group assignment, and not individually per pad.

The different I/O-specific requirements determine the use of different types of I/O cells for the device I/Os. Software controls associated with the signal integrity parameters are implemented at the CTRL_MODULE_CORE_PAD and CTRL_MODULE_WKUP_PAD level.

The following types of I/O cells associated with pad groups can be identified:

- LPDDR2/DDR3 high-speed I/O cells with impedance (I), slew rate (SR), and weak driver (WD) settings
- SMART I/O cells for most of the pads with slew rate control (SC) and drive strength (DS) control settings
- I2Cx I/O cells with pullup resistance versus capacitance load (LB), glitch free operation (GLFENB) and PULLUPRESX settings
- Extended drain I/O cells for sdcard pads. For more information, see Section 18.4.9, *Extended-Drain I/O and PBIAS Cell*
- Glitch Free I/O cells only for pads sys_nrespwron and sys_nreswarm

NOTE: Unlike most of the I/O cells, the glitch free I/O cell does not have signal integrity or dual voltage group control settings.

NOTE: C_{LOAD} is the total capacitance seen at the far end of the transmission line.

NOTE: I/Os are non-failsafe, meaning one must never apply voltage at a pad before the internal I/O supply voltage VDDS is powered.

The pad group-assigned signal integrity controls are provided through the registers described in Table 18-72.

Table 18-72. Signal Integrity Parameter Control Registers

18.4.12.7.2 High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings

The LPDDR2/DDR3 buffers are based on 1.2-V high-speed unterminated logic and require excellent driver impedance control to achieve optimal timing-EMI trade-offs. A specific type of device I/O cells with programmable features are used to meet this requirement. These I/O cells support 1.2-V operation. These cells are also provided with additional features to support the high-speed inter-chip (HSIC) interface.

Two types of software-configurable I/O cells are integrated to support high-speed unterminated logic:

- Single-ended I/O cells
- Two-pad differential I/O cells

Two-pad differential I/O cells are provided with a differential receiver and complementary transmitter. They are used to support the LPDDR2/DDR3 clock pads and LPDDR2/DDR3 strobe pads.

The LPDDR2/DDR3 I/O cells are integrated with the following controls in the CTRL_MODULE_CORE_PAD module:

- Driver output impedance (I) controls
- SR controls
- WD controls to support LPDDR2/DDR3/HSIC interface and avoid floating pad
- Process-only impedance compensation using 5-bit binary coded schema separately for pullup p<1:5> and pulldown n<1:5> impedance

Programmable bits for impedance and SR control are provided when the I/Os are set to operate in driver mode (outputs).

The bits I[2:0] are used to program the desired impedance value of the driver. Table 18-73 describes the driver impedance settings.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 18-73. Driver Impedance Output Settings

I[2]	I[1]	I[0]	Drive Setting Name
0	0	0	Drv5
0	0	1	Drv6
0	1	0	Drv7
0	1	1	Drv8
1	0	0	Drv9
1	0	1	Drv10
1	1	0	Drv11
1	1	1	Drv12

NOTE:

- Table 18-73 is valid for pullup and pulldown outputs.
- For all electrical characteristics please see the Electrical Characteristics / DC Electrical Characteristics section of the device Data Manual.

To achieve optimal noise/speed trade off, the slew rate of the output signal can also be programmed using the slew rate (turn-on time) control bits SR[2:0]. The SR settings in Table 18-74 do not affect the driver DC drive strength. They control only the driver turn-on time.

Table 18-74. Driver Slew Rate Settings

SR[2]	SR[1]	SR[0]	Turn-On Time Level	Note
0	0	0	fastest	All 8 values are valid.
...	...	...		
...	...	...		
1	1	1	slowest	

Weak pullup or pulldown or a keeper on pad is enabled through the WD[0] and WD[1] bits. The weak pullup or pulldown option is used to define the pad state (high or low) when no signal is driving the pad. The weak keeper option is used to maintain the previous output value when nothing is driving the pad. Table 18-75 describes the WD controls.

NOTE: The WD[1:0] bit field controls play the role of the PULLTYPESELECT and PULLUDENABLE bits within the standard pad configuration registers, and provides the keeper function to the I/Os with the state WD = 0b11.

Similar to the ddr1_x, ddr2_x and ddr3_x pads, the usbb1_hsic_data/strobe, usbb2_hsic_data/strobe, and usbb3_hsic_data/strobe pads also have weak driver software controls. They are in the CONTROL_SMART3IO_PADCONF_1 register.

Table 18-75. Weak Driver PUPD/Latch Mode

WD[1]	WD[0]	Operation
0	0	Pull logic disabled
0	1	Weak pullup enabled
1	0	Weak pulldown enabled
1	1	Weak keeper enabled

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: To avoid unnecessary power consumption, software must overwrite the Weak Driver (WD) reset values by setting them to 0x0.

NOTE: There is no software control (INPUTENABLE) for the input buffer of the high-speed unterminated logic I/Os associated with the ddr, usbb_hsic_data/strobe pads. If the CMOS buffer is enabled, it is always bidirectional (that is, the input buffer is always enabled).

18.4.12.7.3 SMART I/O Buffers with Slew Rate and Drive Strength Control Settings

Most of the device pads are associated with SMART I/O cells. The SMART I/O cell includes an output buffer which has programmable slew rate and drive strength controls (SC and DS bits, respectively).

There are three programmable slew rate levels for these I/Os. Based on the required AC performance, the slew rate selection is done for a given group of I/Os through the CONTROL_SMART2IO_PADCONF_0, CONTROL_SMART2IO_PADCONF_1 and CONTROL_SMART2IO_PADCONF_2 registers in the CORE power domain and the CONTROL_SMART1NOPMIO_PADCONF_1 registers located in the WKUP power domain. For the different groups of pads and corresponding signal integrity control registers, see Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*.

Table 18-76 provides the slew rate control settings that are selectable through the SC[1:0] bit field.

Table 18-76. Slew Rate Control Settings

SC1 Bit	SC0 Bit	Slew Rate Control Mode
0	0	slow
0	1	medium
1	0	high
1	1	Not applicable

The SMART I/O output buffer has four programmable drive strength levels. The drive strength selection is done for a given group of I/Os through the CONTROL_SMART1IO_PADCONF_0, CONTROL_SMART1IO_PADCONF_1, and CONTROL_SMART1IO_PADCONF_2 registers in the CORE power domain, and the CONTROL_SMART1NOPMIO_PADCONF_0 registers in the WKUP power domain. For the different groups of pads and corresponding signal integrity control registers, see Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*.

Table 18-77 provides the drive strength control settings selectable through the DS[1:0] bit fields.

Table 18-77. Drive Strength Control Settings

DS1	DS0	Drive Strength Control Mode
0	0	Maximum output buffer resistance
0	1	
1	0	
1	1	Minimum output buffer resistance

NOTE: For all electrical characteristics please see the device Data Manual.

18.4.12.7.4 I2Cx I/Os Group PULLUPRESX Controls and Load Range Settings

The I2Cx buffer contains internal pullup resistors for FS and HS modes. The I2Cx_LB (where x = 1 to 5) bit fields in the CONTROL_SMART3IO_PADCONF_0 register are used to select an appropriate pullup resistor for a given load range. These pullup resistors can be enabled or disabled through the I2Cx_SDA_PULLUPRESx and I2Cx_SCL_PULLUPRESx (where x = 1 to 5) bits, which reside in the CONTROL_I2C_0 register. In the same register, the active high I2Cx_SDA_GLFENB and I2Cx_SCL_GLFENB bits are implemented for I^2C receivers to enable glitch-free operation.

The CONTROL_SMART1NOPMIO_PADCONF_0[7:6] SR_LB bit field is used to select an appropriate pullup resistor value for SR PMIC I2C. The SR PMIC associated internal pullup resistors can be enabled and disabled through the CONTROL_I2C_2[30] SR_PMIC_SDA_PULLUPRESX and CONTROL_I2C_2[28] SR_PMIC_SCL_PULLUPRESX bits. Setting the CONTROL_I2C_2[31] SR_PMIC_SDA_GLFENB and CONTROL_I2C_2[29] SR_PMIC_SCL_GLFENB bits enables glitch-free operation.

NOTE: The pullup-versus-load settings applicable to I2Cx FS mode also apply to I2Cx standard speed mode.

NOTE: PULLUDENABLE must be set to 0b0 in the I2Cx pad configuration registers (disable internal weak pullup resistors on I2Cx pads) to ensure the full I/O cell performance capabilities of the I^2C.

NOTE: For all electrical characteristics and different modes settings, see the device Data Manual.

18.4.12.7.5 Device Interfaces Signal Group Controls Mapping

Table 18-78 through Table 18-96 describe the mapping of the signal integrity control bit fields in the different signal integrity control registers described in Table 18-72.

NOTE: The same I/O cell and I/O cell controls assigned to a pad signal available when MUXMODE = 0 are shared between signals available on the same pad when MUXMODE is selected different than 0. For more information, see Section 18.4.8.3, *Pad Multiplexing Register Fields*.

18.4.12.8 Dual Voltage-Supplied Peripheral Controls

Some of the peripheral I/Os have the option to be supplied with a 1.2-V or 1.8-V power supply (VDDS through device external pads). The power supply level to the dual-voltage I/Os of different peripherals is configurable through bit fields in the CONTROL_PADCONF_MODE register in the CORE domain (Camera TCTRL i/f, GPIO, I2C2, I2C3, I2C4, I2C5, Timers, ABE modules i/f, SDIO/MMC2, SDIO/MMC3, MCSPI1, MCSPI2, DSI, UART1, UART2, UART3, UART5, UART6, HSI1, HSI2, HDMI) and the CONTROL_WKUP_PADCONF_MODE register in the WKUP domain (I2C1 i/f, Power management IC i/f, system i/f). One control bit in these registers is dedicated to set dual-voltage per group of pads.

Table 18-97 describes dual-voltage controls versus the mapping of different pads.

Table 18-97. Dual-Voltage Peripheral Control Bits vs Pad Mapping

Dual-Voltage VDDS = 1.2-V/1.8-V Control Bits	Pads With Dual-Voltage Settings

18.5 Control Module Programming Guide

18.5.1 Control Module Low-Level Programming Models

This section describes the low-level programming sequences for the configuration and use of the control module.

18.5.1.1 Global Initialization

18.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the control module is used for the first time after a device reset. This initialization of surrounding modules is based on the environment and integration of the control module. For more information, see *Section 18.2, Control Module Environment*, and Section 18.3, *Control Module Integration*.

Table 18-98. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The three clocks coming from the PRCM module (L4CFG_L4_GICLK, WKUPAON_GICLK, and L3INSTR_TS_GCLK) are not software-controlled by PRCM. For more information about the three clocks, see Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.
L4 interconnect	For information about the L4_CFG interconnect configuration, see Section 14.3, *L4 Interconnects*.

18.5.1.1.2 Control Module Global Initialization

18.5.1.1.2.1 Software Reset

The control module is not sensitive to a software reset.

18.5.1.2 Operational Modes Configuration

18.5.1.2.1 Extended-Drain I/Os and PBIAS Cells Programming Guide

This section describes the programming flow from 3.0 V to 1.8 V, and vice versa, when operating with the extended-drain I/Os and PBIAS cells. Figure 18-20 shows the interrup-method configuration of the PBIAS cell for operation in different modes. Table 18-99 lists the registration settings for configuring the SDCARD_PBIAS cell and SDCARD extended-drain I/O cell.

PRELIMINARY

Figure 18-20. Configuring PBIAS Cell to Operate in Different Modes, Interrupt Method

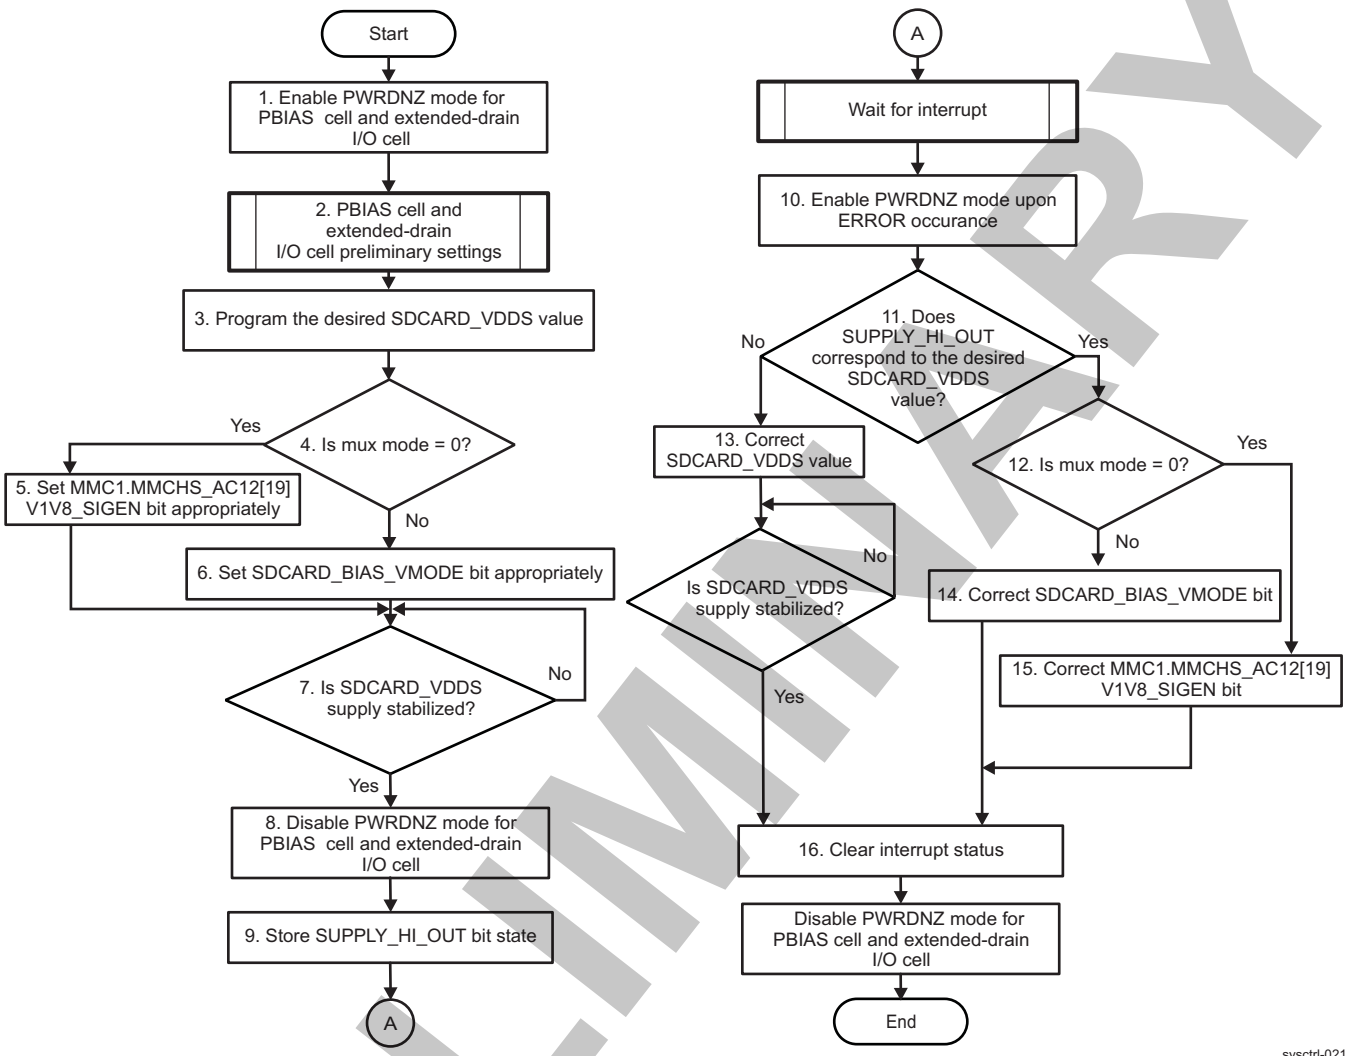

Table 18-99. Register Settings for Configuring the SDCARD_PBIAS Cell and SDCARD Extended-Drain I/O Cell

Procedure Name	Description	Register Settings
1. Enable PWRDNZ mode for PBIAS cell and extended-drain I/O cell.	Software must keep SDCARD_PBIAS cell and SDCARD extended-drain I/O cell PWRDNZ signals low whenever SDCARD_VDDS ramps up/down or changes. This is for cell protection purposes.	1. Set CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ = 0b0. 2. Set CONTROL_PBIAS[27] SDCARD_BIAS_PWRDNZ = 0b0.
2. Preliminary SDCARD_PBIAS cell and SDCARD extended-drain I/O cell settings.	Enable SDCARD_PBIAS cell output and SDCARD_PBIAS error associated interrupt. Select desired I/Os within the SDCARD I/O cell and set the corresponding pad configuration fields appropriately.	1. Set CONTROL_PBIAS[25]SDCARD_BIAS_HIZ_MODE = 0b0. 2. For more information about setting MPU_IRQ_75 line-associated interrupt request PBIAS_IRQ, see Chapter 17, *Interrupt Controllers*. 3. For I/O multiplexing and pad configuration settings, see Section 18.5.1.2.3, *Pad Configuration Programming Points*.
3. Program the desired SDCARD_VDDS voltage for MMC/SD/SDIO1 I/Os.	Program external power supply IC to generate appropriate SDCARD_VDDS voltage (3.0 V or 1.8 V).	For more information about I^2C interface operation, see Section 23.1.1, *HS I2C Overview*.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 18-99. Register Settings for Configuring the SDCARD_PBIAS Cell and SDCARD Extended-Drain I/O Cell (continued)

Procedure Name	Description	Register Settings
4. Check whether MUXMODE is set to 0 or not.	When mux mode is set to 0 sdcard_i signals are muxed on the pads and SDCARD_BIAS_VMODE does not apply. In this case MMC1.MMCHS_AC12[19] V1V8_SIGEN applies.	CONTROL_CORE_PAD0_X_PAD1_Y.MUXMODE = 0x-
5. Set V1V8_SIGEN bit appropriately.	PBIAS voltage generation is based on the value of V1V8_SIGEN, set according to externally applied SDCARD_VDDS voltage.	MMC1.MMCHS_AC12[19] V1V8_SIGEN = 0b- (1)
6. Set SDCARD_BIAS_VMODE bit appropriately.	PBIAS voltage generation is based on the value of SDCARD_BIAS_VMODE, set according to externally applied SDCARD_VDDS voltage.	Set CONTROL_PBIAS[21] SDCARD_BIAS_VMODE = 0b- (2).
7. Check whether the SDCARD_VDDS supply is stabilized.	Check the state of the externally generated SDCARD_VDDS voltage, which is provided through communication between the device and external power supply device over the I^2C interface.	For more information about I^2C interface settings, see Section 23.1.1, *HS I2C Overview*.
8. Disable PWRDNZ mode for SDCARD_PBIAS cell and extended-drain I/O cell	This starts the SDCARD_PBIAS cell work to generate the PBIAS voltage.	1. Set CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ = 0b1. 2. Set CONTROL_PBIAS[27] SDCARD_BIAS_PWRDNZ = 0b1.
9. Store the state of the SUPPLY_HI_OUT bit.	Done as a preliminary step for error-handling analysis. (Whenever PWRDNZ = 0b0, SUPPLY_HI_OUT is unconditionally set to 0b0.)	Store the CONTROL_PBIAS[24] SDCARD_BIAS_SUPPLY_HI_OUT bit in memory.
10.Enable PWRDNZ mode upon error occurrence.	It is recommended that all the I/Os are powered down (PWRDNZ = 0) as soon as VMODE_ERROR is high.	1. Set CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ = 0b0 2. Set CONTROL_PBIAS[27] SDCARD_BIAS_PWRDNZ = 0b0.
11. Does SUPPLY_HI_OUT correspond to the desired SDCARD_VDDS?	Test whether the error comes from incorrectly set value of SDCARD_VDDS or incorrectly set VMODE bit.	Check the SUPPLY_HI_OUT bit stored in memory.
12. Check whether MUXMODE is set to 0 or not.	When muxmode is set to 0, sdcard_i signals are muxed on the pads and SDCARD_BIAS_VMODE does not apply. In this case MMC1.MMCHS_AC12[19] V1V8_SIGEN applies.	CONTROL_CORE_PAD0_X_PAD1_Y.MUXMODE = 0x-
13. Correct SDCARD_VDDS value.	If SUPPLY_HI_OUT is different from expected, correct and set SDCARD_VDDS value over I^2C again.	For more information about I^2C interface settings, see Section 23.1.1, *HS I2C Overview*.
14. Correct SDCARD_BIAS_VMODE bit.	If the level of SUPPLY_HI_OUT corresponds to the desired value of SDCARD_VDDS, correct the value of the SDCARD_BIAS_VMODE bit.	Modify the value of the CONTROL_PBIAS[21] SDCARD_BIAS_VMODE bit.
15. Correct V1V8_SIGEN bit.	If the level of SUPPLY_HI_OUT corresponds to the desired value of SDCARD_VDDS, correct the value of the V1V8_SIGEN bit.	Modify the value of the MMC1.MMCHS_AC12[19] V1V8_SIGEN bit.
16. Clear interrupt status.	Clear the MPU_IRQ_75 interrupt status flag.	For more information about setting the MPU_IRQ_75 line associated interrupt request PBIAS_IRQ, see Section 17.1, *Interrupt Controllers Overview*.

(1) Must be set low when the external SDCARD_VDDS source is programmed to be 3.0 V, or set to high when the external SDCARD_VDDS source is programmed to be 1.8 V. The reset default value corresponds to 3.0 V.

(2) Must be set high when external SDCARD_VDDS source is programmed to be 3.0 V, or low when the external SDCARD_VDDS source is programmed to be 1.8 V. The reset default value corresponds to 3.0 V.

18.5.1.2.2 Hardware Observability Settings

This section describes the procedures to control the hardware observability features of the device. To configure these features, the programmer must perform the steps listed in Table 18-100.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

Table 18-100. Configure Hardware Observability Features

	Step	Register/Bit Field/Programming Model	Value
1.	Select the hwobs(0)/hwobs(1)/hwobs(2) signal frequency divider value (applies only to po_hw_dbg0, po_hw_dbg1, and po_hw_dbg2 bus signals propagated in the CORE power domain).	CONTROL_HWOBS_CONTROL[7:3] HWOBS_CLKDIV_SEL CONTROL_HWOBS_CONTROL[13:9] HWOBS_CLKDIV_SEL_1 CONTROL_HWOBS_CONTROL[18:14] HWOBS_CLKDIV_SEL_2	0x- (1)
2.	Enable/disable gating of hwobs and alternatively set all hwobs ports to 0 or 1.	.CONTROL_HWOBS_CONTROL[2] HWOBS_ALL_ZERO_MODE CONTROL_HWOBS_CONTROL[1] HWOBS_ALL_ONE_MODE	0x- (2)
3.	Enable/disable hwobs port gating only for signals coming from IPs identified in the MACRO group (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_HWOBS_CONTROL[0] HWOBS_MACRO_ENABLE	0x- (3)
4.	Associate a certain hwobs channel to the CORE or WKUP power domain.	Configure each bit from the CONTROL_DEBOBS_FINAL_MUX_SEL[31:0] SELECT bit field appropriately for its corresponding hw_dbg channel.	0x-
5.	Choose the source of a signal or signal view channel in the CORE power domain.	Configure each CONTROL_CORE_CONF_DEBUG_SEL_TST_0[3:0] MODE through CONTROL_CORE_CONF_DEBUG_SEL_TST_31[3:0] MODE bit field appropriately for its corresponding hw_dbg channel.	0x-
6.	Choose the source of a signal within the WKUP power domain.	Configure each CONTROL_WKUP_CONF_DEBUG_SEL_TST_i[1:0] MODE bit field, (where i = 0 to 31) appropriately for its corresponding hw_dbg channel i (where i = 0 to 31).	0x-
7.	Choose to associate a certain DPLL signal to a given DPLL signal view channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_DPLL_FREQLOCK_SEL[3:0] MULT CONTROL_CONF_DPLL_TINITZ_SEL[3:0] MULT CONTROL_CONF_DPLL_PHASELOCK_SEL[3:0] MULT CONTROL_CONF_DPLL_TENABLE_SEL[3:0] MULT CONTROL_CONF_DPLL_TENABLEDIV_SEL[3:0] MULT CONTROL_CONF_DPLL_BYPASSACK_SEL[3:0] MULT CONTROL_CONF_DPLL_IDLE_SEL[3:0] MULT	0x-
8.	Choose to associate a certain DPLL controller signal to a given DPLL controller signal view channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_DPLLCTRL_PLLLOCK_SEL[2:0] MULT CONTROL_CONF_DPLLCTRL_PLLRECAL_SEL[2:0] MULT CONTROL_CONF_DPLLCTRL_STOPCLOCK_SEL[2:0] MULT CONTROL_CONF_DPLLCTRL_STOPCLOCKACKZ_SEL[2:0] MULT	0x-
9.	Choose to associate a certain MMCx power-management signal to a given MMCx power-management signal view channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_MMCX_ADPIDLE_SEL[2:0] MULT CONTROL_CONF_MMCX_ADPDAT1PADEN_SEL[2:0] MULT CONTROL_CONF_MMCX_OCPL4IDLEREQ_SEL[2:0] MULT CONTROL_CONF_MMCX_OCPL3MWAIT_SEL[2:0] MULT CONTROL_CONF_MMCX_PIRFFRET_SEL[2:0] MULT CONTROL_CONF_MMCX_OCPL4SIDLEACKO1_SEL[2:0] MULT CONTROL_CONF_MMCX_OCPL4SIDLEACKO0_SEL[2:0] MULT CONTROL_CONF_MMCX_OCPL3MSTANDBYO_SEL[2:0] MULT CONTROL_CONF_MMCX_SWAKEUP_SEL[2:0] MULT	0x-
10.	Choose to associate a certain clockout signal to a given clockview channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_CLK_SEL0[3:0] MULT through CONTROL_CONF_CLK_SEL2[3:0] MULT	0x-
11.	Choose to associate an sDMA signal to a given sDMA view channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_SDMA_REQ_SEL0[6:0] MULT through CONTROL_CONF_SDMA_REQ_SEL3[6:0] MULT	0x-

(1) To configure the hwobs(0) channel to operate normally, the value of the HWOBS_CLKDIV_SEL, HWOBS_CLKDIV_SEL_1, or HWOBS_CLKDIV_SEL_2 bit must be set different than 0.

(2) Set both bits to 0 to enable hardware observability. Set only one bit to 1 to gate hwobs ports according to the output state required.

(3) The following subsystems belong to this group: MPU subsystem, IVA and ABE.

PRELIMINARY

Table 18-100. Configure Hardware Observability Features (continued)

	Step	Register/Bit Field/Programming Model	Value
12.	Set the appropriate pad configuration bit fields to associate the hw_dbgn pad function to output pins and configure additional output pad features.	For more information, see Section 18.4.11, *Hardware Observability*, and Section 18.4.8, *Pad Functional Multiplexing and Configuration*.	For more information, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*.

For more information about the different functions and registers associated with the hardware observability features, see Section 18.4.11, *Hardware Observability*.

18.5.1.2.3 Pad Configuration Programming Points

This section uses an example to describe the configurations of pads necessary for working in active mode.

Perform the follwing steps to configure the pad:

1. Identify interface signals required from the target application.

   Example: Configure the UART3 interface with the required signals: uart3_rx_irrx, uart3_tx_irtx, uart3_cts_rctx, and uart3_rts_irsd.

2. Choose the pads used for those signals. Some signals may be available on several pads and/or may be multiplexed with other signals needed for another application. See Section 18.4.8.3, *Pad Multiplexing Register Fields*.

   Example: Unlike the uart3_rx_irrx and uart3_tx_irtx signals, each of which is available on three pads, the uart3_cts_rctx and uart3_rts_irsd signals are available only on one pad each (MUXMODE = 0x0).

   However, on pad uart3_rx_irrx, the uart3_rx_irrx signal is multiplexed with the sdio4_cmd signal (MUXMODE = 0x4), and on pad uart3_tx_irtx, the uart3_tx_irtx signal is multiplexed with the sdio4_clk signal. The uart3_rx_irrx and uart3_tx_irtx pads are the only pads on which the sdio4_cmd and sdio4_clk signals are available in the device, respectively. Assuming that the SDIO4 interface is required in the system along with UART3 interface, the only way is to choose to multiplex uart3_tx_irtx and uart3_rx_irrx on other pads.

   To preserve SDIO4 capability, the uart3_rx_irrx and uart3_tx_irtx signals can be remapped on alternative pads of the device (for example, the rfbi_data1 and rfbi_data2 pads [with MUXMODE set to 0x4 in the corresponding padconfiguration registers]).

3. Identify the signal integrity parameter settings (drive strength, impedance, slew rate, pullup and pulldown strength, and so forth) necessary for the pads associated with I/O cells, listed in Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*).

   For the register settings of the signal integrity parameters for the uart3_cts_rctx and uart3_rts_irsd pads, see Table 18-85. According to the table, the assigned to uart3_cts_rctx and uart3_rts_irsd pads, software signal parameter controls are:

- CONTROL_SMART1IO_PADCONF_1[7:6] UART3_PART1_DS
- CONTROL_SMART2IO_PADCONF_1[5:4] UART3_PART1_SC

   According to Table 18-85, for the sdio4_clk and sdio4_cmd (available on pads uart3_tx_irtx and uart3_rx_irrx when corresponding padconfiguration MUXMODE bit field is set to 0x4), the following bit fields should be set to tune signal performance:

  - CONTROL_SMART1IO_PADCONF_1[5:4] UART3_PART2_DS
  - CONTROL_SMART2IO_PADCONF_2[31:30] UART3_PART2_SC

   Assuming the uart3_rx_irrx and uart3_tx_irtx signals are mapped on the rfbi_data1 and rfbi_data2 pads (MUXMODE set to 0x4), the following signal integrity parameter control bit fields must be set appropriately:

- CONTROL_SMART1IO_PADCONF_2[19:18] DSS_PART2_DS

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- CONTROL_SMART2IO_PADCONF_0[3:2] DSS_PART2_SC.

NOTE: To identify the signal-associated I/O cell signal parameter settings in Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, the user must search for the device pad name on which the desired signal is muxed, because the I/O cell settings are designated and listed on a per-pad basis. This means that a signal name does not appear (unless MUXMODE = 0x0) in Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, but only the name of the pad on which the signal is muxed. Pads that do not have software I/O cell signal integrity parameter controls are not listed in Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*.

Assume the user application configures the kpd_row6 and kpd_row7 signals on the c2c_datain6 and c2c_datain7 pads (MUXMODE = 0x3). The I/O cell signal parameter control bit fields CONTROL_SMART1IO_PADCONF_0[19:18] C2C_PART1_DS and CONTROL_SMART2IO_PADCONF_0[19:18] C2C_PART1_SC listed in Table 18-79 also apply to the kpd_row6 and kpd_row7 signals.

For recommendations about the mentioned pad group signal integrity parameter settings, see the device data manual.

4. Identify and program the peripheral dual-voltage settings, if they apply to the chosen pads. Table 18-97 lists the corresponding control bits of the pads in the CTRL_MODULE_CORE_PAD.CONTROL_PADCONF_MODE and CTRL_MODULE_WKUP_PAD.CONTROL_WKUP_PADCONF_MODE registers.

The identification of the I/O dual-voltage domains control bits for a signal must be made on a per-pad basis.

The I/O supply voltage (1.2 V/1.8 V) for pads uart3_cts_rctx, uart3_rts_irsd, uart3_rx_irrx (signal sdio4_cmd), and uart3_tx_irtx (signal sdio4_clk) is configured by setting the CTRL_MODULE_CORE_PAD.CONTROL_PADCONF_MODE[23] VDDS_21_MODE bit. Because the uart3_rx_irrx and uart3_tx_irtx signals are multiplexed on the rfbi_data1 and rfbi_data2 pads in MUXMODE = 0x4, the dual-voltage control for these uart3 signals is the dual-voltage control corresponding to the pads – CTRL_MODULE_CORE_PAD.CONTROL_PADCONF_MODE[18] VDDS_9_MODE.

For more information about pad performance dependencies from I/O dual-voltage supply settings, see the device data manual.

5. Identify the pad configuration registers associated with the pads to be used in the application. See Section 18.4.8.3, *Pad Multiplexing Register Fields*.

Example: Under the previous hypothesis, the pad configuration registers to program are:

- uart3_cts_rctx (MUXMODE = 0x0): CONTROL_CORE_PAD0_UART6_RTS_PAD1_UART3_CTS_RCTX[31:16]
- uart3_rts_irsd (MUXMODE = 0x0): CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[15:0]
- uart3_rx_irrx (MUXMODE = 0x4): CONTROL_CORE_PAD0_RFBI_DATA1_PAD1_RFBI_DATA0[15:0]
- uart3_tx_irtx (MUXMODE = 0x4): CONTROL_CORE_PAD0_RFBI_DATA3_PAD1_RFBI_DATA2 [31:16]
- sdio4_clk (MUXMODE = 0x4): CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[31:16]
- sdio4_cmd (MUXMODE = 0x4): CONTROL_CORE_PAD0_UART3_RX_IRRX_PAD1_USBB3_HSIC_STROBE[15:0]

Table 18-101. Active Pads Configuration Points

Step	Register/Bit Field/Programming Model	Value
1. Identify the interface signals and map them to the appropriate pads according to the application requirements and the device-specific pad I/O muxing capabilities. See Section 18.4.8.3, *Pad Multiplexing Register Fields*.	Define the list of I/O signal names: uart3_cts_rctx, uart3_rts_irsd, uart3_rx_irrx, uart3_tx_irtx, sdio4_clk and sdio4_cmd. Define the list of corresponding pads used by application: uart3_cts_rctx, uart3_rts_irsd, rfbi_data1, rfbi_data2, uart3_tx_irtx, and uart3_rx_irrx, respectively	–
2. Identify the corresponding I/O cell signal integrity parameter controls for the pad (on a per-pad basis). See Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*.	(uart3_cts_rctx, uart3_rts_irsd pads) CONTROL_SMART1IO_PADCONF_1[7:6] UART3_PART1_DS CONTROL_SMART2IO_PADCONF_1[5:4] UART3_PART1_SC (uart3_rx_irrx, uart3_tx_irtx pads) CONTROL_SMART1IO_PADCONF_1[5:4] UART3_PART2_DS CONTROL_SMART2IO_PADCONF_2[31:30] UART3_PART2_SC (rfbi_data1, rfbi_data2 pads) CONTROL_SMART1IO_PADCONF_2[19:18] DSS_PART2_DS CONTROL_SMART2IO_PADCONF_0[3:2] DSS_PART2_SC	For more information about the recommended I/O settings, see the device data manual
3. Determine whether the pad is associated with a peripheral dual-voltage domain (see the device data manual). Identify its corresponding 1.2-V/1.8-V dual-voltage control bit in the CTRL_MODULE_CORE_PAD.CONTROL_PADCONF_MODE or CTRL_MODULE_WKUP_PAD.CONTROL_PADCONF_MODE registers. For more information, see Table 18-97.	(uart3_cts_rctx, uart3_rts_irsd, uart3_rx_irrx, uart3_tx_irtx) CTRL_MODULE_CORE_PAD.CONTROL_PADCONF_MODE[23] VDDS_21_MODE (rfbi_data1, rfbi_data2) CTRL_MODULE_CORE_PAD.CONTROL_PADCONF_MODE[18] VDDS_9_MODE	For more information about the I/O performance dependency on dual-voltage settings, see the device data manual.
4. Configure MUXMODE field in pad configuration registers associated with the pads used.	(signal uart3_cts_rctx) CONTROL_CORE_PAD0_UART6_RTS_PAD1_UART3_CTS_RCTX[18:16] UART3_CTS_RCTX_MUXMODE	0x0
	(signal uart3_rts_irsd) CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[2:0] UART3_RTS_IRSD_MUXMODE	0x0
	(signal sdio4_clk) CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[18:16] UART3_TX_IRTX_MUXMODE	0x4
	(signal sdio4_cmd) CONTROL_CORE_PAD0_UART3_RX_IRRX_PAD1_USBB3_HSIC_STROBE[2:0] UART3_RX_IRRX_MUXMODE	0x4
	(signal uart3_rx_irrx) CONTROL_CORE_PAD0_RFBI_DATA1_PAD1_RFBI_DATA0[2:0] RFBI_DATA1_MUXMODE	0x4
	(signal uart3_tx_irtx) CONTROL_CORE_PAD0_RFBI_DATA3_PAD1_RFBI_DATA2[18:16] RFBI_DATA2_MUXMODE	0x4

	CONTROL_CORE_PAD0_RFBI_DATA3_PAD1_RFBI_DATA2[19] RFBI_DATA2_PULLUDENABLE	0x-
7. Set the direction of the pin signal.(2)	CONTROL_CORE_PAD0_UART6_RTS_PAD1_UART3_CTS_RCTX[24] UART3_CTS_RCTX_INPUTENABLE	0x-
	CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[8] UART3_RTS_IRSD_INPUTENABLE	0x-
	CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[24] UART3_TX_IRTX_INPUTENABLE	0x-
	CONTROL_CORE_PAD0_UART3_RX_IRRX_PAD1_USBB3_HSIC_STROBE[8] UART3_RX_IRRX_INPUTENABLE	0x-
	CONTROL_CORE_PAD0_RFBI_DATA1_PAD1_RFBI_DATA0[8] RFBI_DATA1_INPUTENABLE	0x-
	CONTROL_CORE_PAD0_RFBI_DATA3_PAD1_RFBI_DATA2[24] RFBI_DATA2_INPUTENABLE	0x-
8. Glitch filter enable/disable	The GLITCHGOBBLER bit setting applies to several device pads only (bit is available in several padconfiguration registers, at positions [22] or [6]). It enables/disables I/O cell to filter glitches from outside. The example pads listed in this table do NOT have such setting.	0x-
9. Enable/disable the I/O cell power	CONTROL_CORE_PAD0_UART6_RTS_PAD1_UART3_CTS_RCTX[21] UART3_CTS_RCTX_PWRDOWN	0x-(3)
	CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[5] UART3_RTS_IRSD_PWRDOWN	0x-(3)
	CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[21] UART3_TX_IRTX_PWRDOWN	0x-(3)
	CONTROL_CORE_PAD0_UART3_RX_IRRX_PAD1_USBB3_HSIC_STROBE[5] UART3_RX_IRRX_PWRDOWN	0x-(3)
	CONTROL_CORE_PAD0_RFBI_DATA1_PAD1_RFBI_DATA0[5] RFBI_DATA1_PWRDOWN	0x-(3)
	CONTROL_CORE_PAD0_RFBI_DATA3_PAD1_RFBI_DATA2[21] RFBI_DATA2_PWRDOWN	0x-(3)

(1) It is recommended to use internal pullup/down resistor if pad is used as input and external pullup/down is not used.
(2) If the pad is configured in output mode, the hardware automatically disables the internal weak pullup/down resistors.
(3) Default (power-on reset) value is 0, which corresponds to I/O cell powered on.

PRELIMINARY

NOTE: The order for setting the previous pad configuration bits is not important.

NOTE: If a device pad is left unconnected but power is supplied to the I/O cell, it is recommended to keep the corresponding pad configuration bit, CONTROL_CORE/WKUP_PAD0_X_PAD1_Y.INPUTENABLE, set to 0b0. This keeps the input buffer disabled and reduces static current consumption.

NOTE: I/Os are non-failsafe, which means that voltage must never be applied at a pad before the internal I/O supply voltage VDDS is powered.
